15th World Congress on Computational Mechanics

WCCM YOKOHAMA2022 APCOM

8th Asian Pacific Congress on Computational Mechanics

Yokohama Japan Virtual

Congress Vision :
Pursuing the Infinite Potential of Computational Mechanics

July 31 to August 5, 2022
(Pre-Open on July 24)

Apacm iacm JSCES JACM

Book of Abstracts

Supported by JNTO Japan National Tourism Organization

YOKOHAMA JAPAN'S FIRST PORT OF CALL

WCCM-APCOM
YOKOHAMA2022 15th World Congress on Computational Mechanics &
8th Asian Pacific Congress on Computational Mechanics

15th World Congress on Computational Mechanics
&
8th Asian Pacific Congress on Computational Mechanics

Yokohama, Japan
Virtual

Congress vision:

Pursuing the Infinite Potential of Computational Mechanics

July 31 – August 5, 2022
(Pre-Open: July 24)

Hosting Organizations:

International Association for Computational Mechanics (IACM)

The Japan Society for Computational Engineering and Science (JSCES)

Supporting Organizations:

The Asian Pacific Association for Computational Mechanics (APACM)

Japan Association for Computational Mechanics (JACM)

15th World Congress on Computational Mechanics

WCCM YOKOHAMA2022 APCOM

8th Asian Pacific Congress on Computational Mechanics

A publication of:
International Center for Numerical Methods in Engineering (CIMNE)
Barcelona, Spain

ISBN: 978-84-123222-8-6

Printed by: Artes Gráficas Torres S.L., Huelva 9, 08940 Cornellà de Llobregat, Spain

Table of Contents

Organization

Hosting Organizations

International Association for Computational Mechanics (IACM)
The Japan Society for Computational Engineering and Science (JSCES)

Supporting Organizations

The Asian Pacific Association for Computational Mechanics (APACM)
Japan Association for Computational Mechanics (JACM)

Steering Committee

Honorary Chair: Genki Yagawa
Congress Chair: Seiichi Koshizuka
Secretary General, Co-chair: Kenjiro Terada
Co-chair: Kazuo Kashiyama
Co-chair: Marie Oshima
Co-chair: Shinobu Yoshimura

Congress Organizing Committee (COC)

S. Koshizuka (Congress Chair, Japan)
A. Huerta (IACM President, Spain)
O. Allix (IACM Vice President, Europe-Middle East-Africa, France)
J. Fish (IACM Vice President, Americas, USA)
S. Yoshimura (IACM Vice President, Asia Pacific, APACM President, Japan)
J. Dolbow (IACM Secretary General, USA)
K. Kashiyama (APACM Secretary General, Japan)
N. Sasaki (JSCES President, Japan)
H. Okada (JACM President, Japan)
K. Terada (Secretary General, Japan)

Local Organizing Committee (LOC)

S. Koshizuka (Congress Chair)
M. Oshima (Co-chair, Leader of Track 4 in TPC)
K. Kashiyama (Co-chair)
S. Yoshimura (Co-chair)
K. Terada (Secretary General, Co-chair)
Y. Ishitsuka (Deputy Secretary General, JSCES Secretary General)
J. Kato (Deputy Secretary General)
T. Nagashima (Deputy Secretary General)
A. Takahashi (Deputy Secretary General)
D. Isobe (Technical Program Chair, Leader of Track 7 in TPC)
N. Takano (Local Chair)
M. Koishi (Vice-Local Chair)
M. Shirazaki (Secretary-Local)
R. Shioya (Public affairs manager)
M. Asai (Sponsorship manager)
T. Aoki (Leader of Track 1 in TPC)
S. Nishiwaki (Leader of Track 2 in TPC)
A. Matsuo (Leader of Track 3 in TPC)
H. Okada (Leader of Track 5 in TPC)
H. Okuda (Leader of Track 6 in TPC)
T. Hirano (Leader of Track 8 in TPC)

International Advisory Board

A. Huerta (IACM President, Spain)
O. Allix (IACM Vice President, Europe-Middle East-Africa, France)
J. Fish (IACM Vice President, Americas, USA)
S. Yoshimura (IACM Vice President, Asia Pacific; APACM President, Japan)
J. Dolbow (IACM Secretary General, USA)
W. Kam Liu (IACM Past President, USA)
G. Yagawa (IACM Past President, Japan)
E. Oñate (IACM Past President, Spain)
T.J. Oden (IACM Past President, USA)
T.J.R. Hughes (IACM Past President, USA)
K. Kashiyama (APACM Secretary General, Japan)
F. Auricchio (Italy)
M. Behr (Germany)

Technical Program Committee (TPC)

D. Isobe (Technical Program Chair)

(1) Data-Scientific Computational Mechanics

T. Aoki (Leader, Japan)
F. Chinesta (France)
P. Koumoutsakos (USA)
S. Moriguchi (Japan)
R. Onishi (Japan)
K. Schneider (France)
M. Tsubokura (Japan)

(2) Computational Applied Mathematics

S. Nishiwaki (Leader, Japan)
G. Allaire (France)
Y.Y. Kim (Korea)
S. Min (Korea)
E.C.N. Silva (Brazil)
Takayuki Yamada (Japan)
J. Yoo (Korea)
M. Yoshino (Japan)

(3) Computational Fluid Dynamics

A. Matsuo (Leader, Japan)
M.C. Hsu (USA)
S. Kawai (Japan)
B.J. Lee (Korea)
K. Takizawa (Japan)
H. Terashima (Japan)
G. Tryggvason (USA)

(4) Computational Multiphysics

M. Oshima (Leader, Japan)
S. Ii (Japan)
S. Ji (China)
A. Marsden (USA)
M. Sakai (Japan)
A. Yu (Australia)

(5) Computational Solids and Structural Mechanics

H. Okada (Leader, Japan)
L. De Lorenzis (Switzerland)
P. Devloo (Brazil)
C.A. Duarte (USA)
K. Fujisawa (Japan)
Y.T. Gu (Australia)
M. Kurumatani (Japan)
Z. Liu (China)
S. Min (Korea)
D. Okumura (Japan)
J. Soric (Croatia)
T. Takaki (Japan)
V. Tan (Singapore)
S. Tanaka (Japan)
J.P. Yang (Taiwan)
Z. Yosibash (Israel)

(6) Scientific High-performance Computing

H. Okuda (Leader, Japan)
K. Inagaki (Japan)
D. Littlewood (USA)
N. Morita (Japan)
H. Tufo (USA)

(7) Safety & Environmental Engineering

D. Isobe (Leader, Japan)
M. Asai (Japan)
S. Cao (China)
J.S. Chen (USA)
T.S. Han (Korea)
S. Iizuka (Japan)
H.K. Lee (Korea)
M. Papadrakakis (Greece)

(8) Computational Mechanics in Industrial Liaison Activities

T. Hirano (Leader, Japan)
N. Gauger (Germany)
Y. Ito (Japan)
H. Kadowaki (Japan)
M. Maggiore (Belgium)
T. Nagai (Japan)
N. Sasaki (Japan)

Local Executive Committee (LEC)

N. Takano (Local Chair)
M. Koishi (Vice-Local Chair)
M. Shirazaki (Secretary-Local)
M. Asai
H. Fujii
K. Fukagata
R. Higuchi
H. Isakari
K. Iwamoto
J. Kato
M. Kikumoto
K. Matsui
J. Matsumoto
M. Muramatsu
T. Nagashima
Y. Nakabayashi
K. Nakajima
K. Nishiguchi

Plenary and Semi-Plenary Lectures

Plenary Lectures

Designing flexoelectric metamaterials through computational strain gradient engineering

Irene Arias
Lacan, Universitat Politècnica de Catalunya, Spain

Fracture and flow in porous media: a two-scale approach and spline-based discretisation

René de Borst
University of Sheffield, UK

Computational mechanics-based digital twin for model predictive control of autonomous UAV landing in adverse conditions

Charbel Farhat
Stanford University, USA

From engineered metastructures to natural seismic metamaterials: theory, computational aspects and experiments

C.W. Lim
City University of Hong Kong, Hong Kong

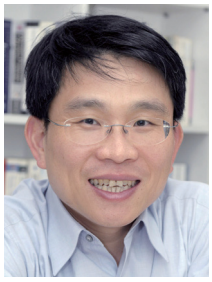
Development of new rocket propulsion system "Rotating Detonation Engine"

Akiko Matsuo
Keio University, Japan

Computational hemodynamics for clinical applications - crossroad between patient-specific simulation and machine-learning techniques

Marie Oshima
The University of Tokyo, Japan

Semi-Plenary Lectures



Deep materials modeling and design

Chuin-Shan (David) Chen
National Taiwan University, Taiwan

Empowering data-informed engineering from smarter data, sensing and hybrid modelling

Francisco Chinesta
ENSAM Institute of Technology, France

Machine-learning based computational mechanics as a powerful tool for engineering and science

YuanTong Gu
Queensland University of Technology, Australia

Discrete crack models in regularized fracture mechanics for mesh-based and mesh-free methods

Michael Kaliske
TU Dresden, Germany

Opportunities for Machine Learning in Computational Mechanics

Ellen Kuhl
Stanford University, USA

On law- and data-based methods

Gui-Rong Liu
University of Cincinnati, USA

A semi-resolved CFD-DEM approach for particulate flows with thermal convection

Moubin Liu
Peking University, China

Hierarchical Deep Learning Neural Network (HiDeNN)-FEM-AI for process design and performance prediction of material systems

Wing Kam Liu
Northwestern University, USA

Recent advances of constitutive models of soft smart materials - from molecular, network scales to continuum scale

Zishun Liu
Xi'an Jiaotong University, China / National University of Singapore, Singapore

Wings at low Reynolds numbers and lifting line theory

Sanjay Mittal
Indian Institute of Technology Kanpur, India

Isogeometric analysis: some recent advances and applications

Alessandro Reali
University of Pavia, Italy

Parametric model order reduction for fluid and structure objects

SangJoon Shin
Seoul National University, Korea

A Topology Optimization Approach Towards Fluid Flow Design Problems

Emilio Silva
Polytechnic School of University of São Paulo, Brazil

Prediction of fatigue crack propagation using effective regularization techniques for regression problems

Yoshitaka Wada
Kindai University, Japan

Virtual elements in engineering sciences

Peter Wriggers
Leibniz University Hannover, Germany

Scientific Contents

PLENARY LECTURES

SEMI-PLENARY LECTURES

MINISYMPOSIA

100 - FRACTURE, DAMAGE AND FAILURE MECHANICS

200 - ADVANCED DISCRETIZATION TECHNIQUES

300 - MULTISCALE AND MULTIPHYSICS SYSTEMS

400 - BIOMECHANICS AND MECHANOBIOLOGY

500 - MATERIALS BY DESIGN

600 - FLUID DYNAMICS AND TRANSPORT PHENOMENA

700 - NUMERICAL METHODS AND ALGORITHMS IN SCIENCE AND ENGINEERING

800 - VERIFICATION AND VALIDATION, UNCERTAINTY EVALUATION AND ERROR ESTIMATION

900 - STRUCTURAL MECHANICS, DYNAMICS AND ENGINEERING

1000 - MANUFACTURING AND MATERIALS PROCESSING

1100 - ATOMISTIC, NANO AND MICRO MECHANICS OF MATERIALS

1200 - MODELING AND ANALYSIS OF REAL WORLD AND INDUSTRY APPLICATIONS

1300 - INVERSE PROBLEMS, OPTIMIZATION AND DESIGN

1400 - SOFTWARE, HIGH PERFORMANCE COMPUTING

1500 - FLUID-STRUCTURE INTERACTION, CONTACT AND INTERFACES

1600 - GEOMECHANICS AND NATURAL MATERIALS

1700 - DATA SCIENCE, MACHINE LEARNING AND ARTIFICIAL INTELLIGENCE

1800 - IMAGING, VISUALIZATION, VIRTUAL REALITY AND AUGMENTED REALITY

2100 - ENVIRONMENTAL, ENERGY AND RESOURCE ENGINEERING

2200 - DISASTER PREVENTION AND MITIGATION, SAFETY PROBLEMS

2300 - INFECTIOUS DISEASES AND ENVIRONMENTAL PROBLEMS

2400 - OTHERS

Contents

PLENARY LECTURES

SEMI-PLENARY LECTURES

MINISYMPOSIA

100 - FRACTURE, DAMAGE AND FAILURE MECHANICS

MS0101 - ADVANCED MATERIALS: COMPUTATIONAL ANALYSIS OF PROPERTIES AND PERFORMANCE

Organized by Vadim V. Silberschmidt and Valery P. Matveenko

MS0103 - Composite materials under crash and impact loading

Organized by Michael May

MS0104 - NUMERICAL SIMULATION AND EXPERIMENT OF CATASTROPHIC FAILURE MECHANICS

Organized by Tiantang Yu and Qingwen Ren

MS0105 - Computational Damage & Fracture Modeling in Multiphysics Framework

Organized by Mostafa Mobasher, Haim Waisman, C. Armando Duarte, Patrice Longère and Sundararajan Natarajan

MS0106 - Crack propagation in multiphysics problems

Organized by Ugo Galvanetto and Bernhard A. Schrefler

MS0107 - Peridynamic Theory and Multiscale Methods for Complex Material Behavior

Organized by Patrick Diehl, Pablo Seleson, Fei Han, Erkan Oterkus and Gilles Lubineau

MS0108 - Recent advances in computational modeling of damage and fracture

Organized by Leong Hien Poh, Ron Peerlings, Tinh Quoc Bui, John Dolbow and Amine Benzerga

MS0109 - Recent Advances in Modeling and Simulating Extreme Events

Organized by Yan Liu, Xiong Zhang, Zhen Chen, Dongdong Wang, Fei Xu and Cheng Wang

MS0110 - CURRENT TRENDS IN PHASE-FIELD MODELING AND COMPUTATION OF FRACTURE & FATIGUE

Organized by Fadi Aldakheel, Ralf Müller and Laura De Lorenzis

MS0112 - DUCTULITY ENHANCEMENT: ADVANCES IN EXPERIMENTAL AND COMPUTATIONAL MECHANICS

Organized by Kaan Inal, Toshihiko Kuwabara, Dirk Mohr and Jidong Kang

MS0113 - Damage and Failure of Composite Materials and Structures

Organized by Stephen Hallett, Joris Remmers and Pedro Camanho

MS0114 - Computational Modelling of Self-healing Composite Materials and Structures

Organized by Ivica Smojver and Vassilis Kostopoulos

MS0115 - Plastic instability and fracture in ductile materials

Organized by Shmuel Osovski, Ankit Srivastava and José A. Rodríguez-Martínez

MS0116 - Multi-stage Failure Simulations

Organized by Mao Kurumatani, Kyoungsoo Park, Kenjiro Terada, Norio Takeuchi and Rene de Borst

MS0117 - Advancement of computational fracture mechanics applications

Organized by Yoshitaka Wada, Hiroshi Okada, Toshio Nagashima, Xueling Fan and Liu Zhanli

MS0118 - Computational analysis of fiber reinforced composites

Organized by Vincent Tan, Ryo Higuchi, Jun Koyanagi and Tong Earn Tay

MS0119 - Ductile-Fracture Modeling and Simulation

Organized by Kazutake Komori

MS0120 - Peridynamics and Nonlocal Theories for Fracture Modelling: Recent Developments and Their Applications

Organized by Satoyuki Tanaka, Tinh Bui Quoc, Selda Oterkus, Erkan Oterkus and Erdogan Madenci

MS0121 - Recent Advances in Computational Fracture Mechanics for Subsurface Applications

Organized by Juan Michael Sargado, Michael Welch and Inga Berre

MS0122 - Fracture, Damage and Failure Mechanics of Smart and Active Materials

Organized by Sergey Kozinov, Bai-Xiang Xu, Andreas Ricoeur, John Huber and Hongjun Yu

MS0123 - Computational Fracture Modeling in Heterogeneous Materials - Recent Advances and Future Challenges

Organized by Paras Kumar, Dhananjay Phansalkar, Julia Mergheim, Sigrid Leyendecker and Paul Steinmann

MS0124 - Modeling of concrete in an Experimental-Virtual-Lab

Organized by Jörg Schröder, Steffen Anders, Dominik Brands, Laura de Lorenzis, Peter Wriggers, Michael Kaliske and Ken Terada

200 - ADVANCED DISCRETIZATION TECHNIQUES

MS0201 - ADVANCES IN THE SCALED BOUNDARY FINITE ELEMENT METHOD AND OTHER SEMI-ANALYTICAL & NUMERICAL TECHNIQUES

Organized by Sascha Eisentraeger, Hauke Gravenkamp, Ean Tat Ooi, Sundararajan Natarajan, Carolin Birk, Sven Klinkel and Chongmin Song

MS0202 - Virtual Element and related polygonal methods in solid and fluid mechanics applica-tions

Organized by Peter Wriggers, Edoardo Artioli and Lourenco Beirão da Veiga

MS0203 - Advances in High-Order Methods for Computational Fluid Dynamics

Organized by Freddie Witherden, Yoshiaki Abe and Peter Vincent

MS0204 - Recent advances in immersed boundary and fictitious domain methods

Organized by Alexander Düster, Oriol Colomës, Sascha Eisenträger, Thomas-Peter Fries, Mats Larson, Mario Ricchiuto, Juan José Rodenas, Riccardo Rossi, Andreas Schröder, Guglielmo Scovazzi and Ernst Rank

MS0205 - Particle-based methods: advances and applications in DEM, PFEM, SPH, MPM, MPS and others

Organized by Sergio Idelsohn, Eugenio Oñate, Eduardo M.B. Campello, Tarek I. Zohdi and Peter Wriggers

MS0206 - Industrial Applications of IGA

Organized by Hugo Casquero, Xiaodong Wei, Emily Johnson, Ming-Chen Hsu, Jessica Zhang, Matt Sederberg and Attila Nagy

MS0207 - Special Methods in Computational Fluid Mechanics

Organized by Matthias Kirchhart and Abhinav Jha

MS0208 - Particle-based methods for computational multi-physics and multi-scale fluid dynamics

Organized by Zhe Ji, Lin Fu and Nikolaus Adams

MS0209 - Current Trends and Advances in Coupled Simulations and Enriched Finite Element Methods

Organized by Olivier Allix, Alejandro Aragon, Daniel Dias-da-Costa and Armando Duarte

MS0210 - Mesh-free particle methods for multi-physics problems

Organized by Ahmad Shakibaeinia and Abbas Khayyer

MS0211 - Isogeometric Spline Techniques on Complex Geometries

Organized by Xiaodong Wei, Deepesh Toshniwal, Hugo Casquero and Yongjie Zhang

MS0213 - Advances and Applications of Collocation Methods: Meshfree, IGA, Machine Learning for PDEs

Organized by Pratik Suchde, Isabel Michel, Elena Atroshchenko and Stéphane P.A. Bordas

MS0214 - CAD-based discretization methods

Organized by Pablo Antolin, Robin Bouclier, Rafael Vázquez Hernández, Thomas Elguedj and Annalisa Buffa

MS0215 - Locking, Stability and Robustness of Non-linear Finite Elements for Large Deformation Problems

Organized by Simon Bieber, Manfred Bischoff, Robin Pfefferkorn, Peter Betsch, Alessandro Reali and Ferdinando Auricchio

MS0217 - HIGH ORDER NUMERICAL METHODS AND HIGH ORDER MESH GENERATION

Organized by Bo Liu, Xuefeng Zhu, Yingjun Wang and Yujie Guo

300 - MULTISCALE AND MULTIPHYSICS SYSTEMS

MS0301 - Mathematical and Mechanical Aspects of Mixed-Dimensional Coupling Problems

Organized by Alexander Popp, Barbara Wohlmuth and Jan Martin Nordbotten

MS0302 - Quasistatic Electromechanics: Methods and Applications

Organized by James Carleton and Wen Dong

MS0303 - Computational interface mechanics in coupled problems

Organized by K. C. Park, C. A. Felippa, Roger Ohayon, Hermann Matthies, José González, Jin-Gyun Kim and Radek Kolman

MS0304 - Multi-scale and machine learning-based modeling methods for optimization and design of composites

Organized by Alfonso Pagani, Marco Petrolo, Maryiam Shakiba and Chao Zhang

MS0305 - MULTIPHYSICS MECHANICS & TRANSPORT PHENOMENA IN SOFT MATERIALS & THEIR INTERFACES: THEORY, SIMULATIONS, & EXPERIMENTS

Organized by HUA LI, BERKIN DORTDIVANLIOGLU, KEK BOON GOH and Eric C.S. Ngin

MS0306 - MULTISCALE COMPUTATIONAL HOMOGENIZATION FOR BRIDGING SCALES IN THE MECHANICS AND PHYSICS OF COMPLEX MATERIALS

Organized by Julien Yvonnet, Kenjiro Terada, Peter Wriggers, Marc Geers and Karel Matous

MS0307 - Multi-scale and Multi-physics Computations in Fluids and Solids

Organized by Yozo Mikata and Glaucio Paulino

MS0308 - Computations in mechanics of metamaterials

Organized by Bilen Emek Abali, Ivan Giorgio and Luca Placidi

MS0310 - Advances in phase-field modelling and simulation

Organized by Akinori Yamanaka, Tomohiro Takaki and Yuhki Tsukada

MS0311 - Performance analysis and degradation studies of photovoltaic modules

Organized by Pattabhi Ramaiah Budarapu, Naresh Varma Datla and Marco Paggi

MS0312 - MULTISCALE COUPLING METHODS FOR MODELING AND SIMULATION OF MATERIALS

Organized by Hao Wang, Huajie Chen and Lei Zhang

MS0313 - Novel Modeling Strategies for Mechatronic Systems

Organized by Florian Toth and Manfred Kaltenbacher

MS0314 - 3D MODELING OF BUILDING MATERIALS: GEOMETRIC AND CONSTITUTIVE ISSUES

Organized by Beatrice Pomaro and Gianluca Mazzucco

MS0315 - Computation for Energy Storage

Organized by Wei Lu

MS0318 - Leveraging Reduced Descriptions to Accelerate Kinetic Simulations

Organized by Lee Ricketson and William Taitano

MS0319 - Integrating Data Science and Multiscale Methods for Multiphysics Applications

Organized by Tim Wildey and Graham Harper

MS0321 - Computational Multiscale Method of Solids and Structures

Organized by Shaoqiang Tang, Shan Tang and Zifeng Yuan

MS0322 - Metamaterials and metasurfaces with odd physical properties

Organized by Yunche Wang and Yu-Chi Su

MS0323 - Multiscale modelling of packing and flow of granular materials

Organized by Zongyan Zhou, Shibo Kuang, Shunying Ji, Qiang Zhou, Xizhong An, Mikio Sakai and Kun Luo

MS0324 - Multiscale and Multiphysics Modelling of the Structural and Mechanical Properties of Energy Storage Materials

Organized by Chih-Hung Chen and Chun-wei Pao

MS0325 - Multiphase flows: experiments, simulations, and modeling

Organized by Fu-Ling Yang and Shu-San Hsiau

MS0326 - Multiscale Procedures in Composites and Heterogeneous Materials

Organized by Paul Steinmann, Guillermo Etse, Daya Reddy and Osvaldo Manzoli

MS0327 - Multiscale Computational Approach and Informatics of Complex Structures and Advanced Materials

Organized by Maenghyo Cho, Seunghwa Yang and Hyunseong Shin

MS0328 - Fundamental numerical methods towards accurate, efficient and practical simulations in industrial, environmental and biological applications

Organized by Satoshi Ii, Ryosuke Akoh, Chungang Chen and Xingliang Li

MS0329 - Multi-scale modelling of generalised continua and metamaterials

Organized by Igor A. Rodrigues Lopes, Francisco M. Andrade Pires and Eduardo de Souza Neto

400 - BIOMECHANICS AND MECHANOBIOLOGY

MS0401 - Computational modelling and machine learning in biomechanics and biomedical engineering

Organized by Chi Wei Ong, Fangsen Cui and Hwa Liang Leo

MS0402 - COMPUTATIONAL BIOMEDICINE AND BIOMECHANICS

Organized by Maxim Solovchuk and Tzyy-Leng Horng

MS0403 - Molecular and Cellular Biomechanics

Organized by Wonmuk Hwang and Mohammad Mofrad

MS0404 - COMPUTATIONAL BIOMECHANICS: ADVANCED METHODS AND EMERGING AREAS

Organized by Alessio Gizzi, Daniel E Hurtado, Michele Marino and Christian J Cyron

MS0405 - Computational Biomechanics and Biomimetics of Flapping Flight

Organized by Daisuke Ishihara, Hao Liu and Shinobu Yoshimura

MS0406 - Female pelvic floor biomechanics

Organized by Elisabete Silva and Luyun Chen

MS0407 - Multiscale Modeling and Machine Learning in Biomechanics

Organized by Yaling Liu, Lucy Zhang, Ying Li and Jianxun Wang

MS0408 - Modelling and simulation of thermo-mechanical effects in excitable tissues

Organized by Ricardo Ruiz Baier, Alessio Gizzi, Leo Cheng and Vijay Rajagopal

MS0409 - Multiphysics and Data-driven Modeling for Cardiovascular Biomedicine

Organized by Debanjan Mukherjee, Adarsh Krishnamurthy and Ming-Chen Hsu

MS0410 - Computational Simulation and Prediction of Injury due to Blast Exposures, and Blunt and Ballistic Impacts

Organized by Gary Tan, Raj Gupta and Amit Bagchi

MS0411 - Computational mechanobiology of musculoskeletal tissues

Organized by Pascal Buenzli, Junning Chen, Hanna Isaksson and Richard Weinkamer

MS0412 - Modeling and simulation of biological cells

Organized by Luoding Zhu and Jared Barber

MS0413 - ADVANCES IN COMPUTATIONAL BIOMECHANICS AND MECHANIOBIOLOGY

Organized by David Pierce, Corey Neu and René Van Donkelaar

MS0414 - Exploring brain mechanics

Organized by Silvia Budday, Kristian Franze, Jochen Guck and Paul Steinmann

MS0415 - Spatial Mechanomics: Tools, methods, and results related to material heterogeneity in biomechanics

Organized by Emma Lejeune, Manuel Rausch, Adrian Buganza Tepole and Johannes Weickenmeier

MS0416 - Imaging-informed computational modeling in medicine

Organized by Rafael Grytz, Jessica Zhang, Michael Girard and Ian Sigal

MS0417 - Computational multiscale modeling in biomechanics

Organized by Li-Wei Liu, Chia-Ching Chou and Shu-Wei Chang

MS0418 - ADVANCES IN CHARACTERIZATION AND MODELING OF BIOLOGICAL SOFT TISSUES

Organized by Tien-tuan Dao and Marie-Christine Ho Ba Tho

MS0420 - Modeling of the cardiovascular and cerebral system with application to clinical medicine

Organized by Masanori Nakamura, Makoto Ohta, Marie Oshima, Juan Cebral, Anne Robertson and Khalid Saqr

MS0421 - Musculoskeletal Biomechanics

Organized by Renate Sachse, Elisabeth Jensen, Rainer Burgkart, Sami Haddadin, Oliver Röhrle and Wolfgang A. Wall

MS0422 - Computational Continuum Biomechanics

Organized by Tim Ricken, Oliver Röhrle and Silvia Budday

MS0423 - Multiscale biofluid mechanics: from cells to organs

Organized by Ken-ichi Tsubota, Ming Dao, Toru Hyakutake and Xiaobo Gong

MS0424 - Computational Mechanics and Mechanobiology of the Shoulder Joint

Organized by Ara Nazarian and Joseph DeAngelis

MS0425 - Musculoskeletal Modeling Across the Lifespan: Biomechanics from Young to Aging to Aged

Organized by Geoffrey Handsfield, Justin Fernandez, Vickie Shim and Thor Besier

MS0426 - In silico clinical trials of cardiac disease

Organized by Nenad Filipovic

500 - MATERIALS BY DESIGN

MS0502 - COMPUTATIONAL MECHANICS OF SOFT MATTER

Organized by Zishun Liu

MS0503 - COMPUTATIONAL DESIGN OF ARCHITECTED MATERIALS

Organized by Julián Norato and José Guedes

MS0504 - Virtual Multi-physics Computational Design and Manufacturing Simulation of Materials and Structures

Organized by Eric Li, JN Reddy, Guirong Liu, CW Lim, Vincent Tan, ZC He, Bing Li, Qiqi Li, Zhuoqun Zheng, Lei Deng and Yi Wu

MS0506 - New Advances in Phase Change Materials

Organized by Santiago Madruga

MS0507 - Multiscale Topology Optimization

Organized by Narasimha Boddeti

MS0508 - Lessons from nature: design of bioinspired architected materials

Organized by Mohammad J. Mirzaali, Mario Milazzo, Flavia Libonati, Davide Ruffoni and Amir A. Zadpoor

600 - FLUID DYNAMICS AND TRANSPORT PHENOMENA

MS0601 - INTERFACIAL FLOW SIMULATION

Organized by Mostafa Safdari Shadloo, Amin Rahmat, Alessio Alexiadis and Mohammad Mehdi Rashidi

MS0602 - Advanced multi-physics CFD simulations in science and engineering

Organized by Takahiro Tsukahara, Kaoru Iwamoto, Koji Fukagata, Mamoru Tanahashi, Nobuyuki Oshima and Makoto Yamamoto

MS0603 - Modelling and simulation of coupled solvent transport and deformation

Organized by Jana Wilmers, Dai Okumura, Laurence Brassart and Nikolaos Bouklas

MS0604 - Granular Flows: Modelling and Computational Challenges

Organized by Thomas Weinhart, Anthony R Thornton and Rudy Valette

MS0605 - COMPLEX FLUID FLOWS IN ENGINEERING: MODELING, SIMULATION AND OPTIMIZATION

Organized by Stefanie Elgeti and Marek Behr

MS0607 - Multiphase flows

Organized by Célio Fernandes, Luís Lima Ferrás and Alexandre Afonso

MS0608 - Fluid Dynamical Laws and Transport Phenomena for Complex Dynamical Systems

Organized by Ricardo Tomás Ferreyra

MS0609 - MODELLING OF ATOMIZATION, BREAKUP AND FRAGMENTATION OF FLUIDS

Organized by Stéphane Zaleski, Junji Shinjo, Leonardo Chirco, Gretar Tryggvason and Shiyi Chen

MS0610 - Modeling and Simulation of Computational Multi-phase Flows

Organized by Yi-Ju Chou and Yang-Yao Niu

MS0611 - Multiphase flows with non-Newtonian materials: simulation, experiment, and machine learning

Organized by Anselmo Pereira, Rudy Valette, Elie Hachem, Manuel Alves and Alvaro Coutinho

MS0612 - Collisional Kinetic modeling in classical and plasma dynamics: numerical methods and non-linear analysis

Organized by Irene M. Gamba, Jeffrey R. Haack and Milana Pavic-Colic

MS0613 - Computational fluid dynamics and heat transfer

Organized by KUANG Lin and Chuan Chieh Liao

700 - NUMERICAL METHODS AND ALGORITHMS IN SCIENCE AND ENGINEERING

MS0701 - Numerical techniques for the simulation and model reduction of complex physical systems

Organized by Thomas Hudson and Xingjie Li

MS0702 - Isogeometric Methods

Organized by Alessandro Reali, Yuri Bazilevs, David J. Benson, RenÃ© de Borst, Thomas J.R. Hughes, Trond Kvamsdal, Giancarlo Sangalli and Clemens V. Verhoosel

MS0703 - Developments and Applications of Discrete Element Method in Modelling and Simulation of Granular Systems

Organized by Xihua Chu, Wenjie Xu, Zongyan Zhou and Mikio Sakai

MS0704 - Stabilized, Multiscale and Multiphysics Methods

Organized by Guillermo Hauke, Arif Masud and Isaac Harari

MS0705 - Domain Decomposition and Large-scale Computation

Organized by MASAO Ogino, Amane Takei, Qinghe Yao and Sin-Ichiro Sugimoto

MS0706 - DATA-BASED ENGINEERING & COMPUTATIONS

Organized by Francisco Chinesta, Elias Cueto, Charbel Farhat, Pierre Ladeveze and Francisco Javier Montans

MS0707 - Advance and Application of Meshfree Methods

Organized by Judy Yang, Chia-Ming Fan, Pai-Chen Guan, Tsung-Hui Huang and Kuan-Chung Lin

MS0709 - Recent Advances in Meshfree and Particle Methods

Organized by Seiya Hagihara, Mitsuteru Asai, Ha Hong Bui, Fei Xu and Seiichi Koshizuka

MS0710 - Computational Particle Dynamics

Organized by Moubin Liu, Dianlei Feng and Christian Weißenfels

MS0711 - Smoothed Finite Element Methods and Other Advanced FEMs

Organized by Yuki Onishi, Gui-Rong Liu, Masaki Fujikawa and Quan Bing Eric Li

MS0712 - Boundary Element Methods and Mesh Reduction Methods

Organized by Xiao-Wei Gao

MS0713 - Advances and Applications of Meshfree and Particle Methods

Organized by Jiun-Shyan Chen, Frank Beckwith, Zhen Chen, Mike Hillman, Marc Schweitzer, Mike Tupek, Dongdong Wang, CT Wu and Pai-Chen Guan

MS0714 - Meshfree and Other Advanced Numerical Methods for Engineering and Applied Mathematical Problems

Organized by Lihua Wang, Chuanzeng Zhang and Zheng Zhong

MS0715 - Multi-scale numerical methods for non-linear solids problems

Organized by Frédéric Lebon and Isabelle Ramière

MS0716 - Model order reduction for parametrized continuum mechanics systems

Organized by Youngsoo Choi, Masayuki Yano and Matthew Zahr

MS0717 - Modeling and Simulation of Polymer Fluids

Organized by Xiaodong Wang, Puyang Gao and Jin Su

MS0719 - ADVANCES IN NUMERICAL METHODS FOR LINEAR AND NON-LINEAR DYNAMICS AND WAVE PROPAGATION

Organized by Alexander Idesman and Hauke Gravenkamp

MS0720 - Numerical models applied in architectonic and engineering design

Organized by Janusz Rębielak

MS0721 - RECENT ADVANCES ON POLYTOPAL METHODS

Organized by Franco Dassi, André Harnist, Xin Liu and Ilario Mazzieri

MS0722 - High-order numerical methods for compressible flow and turbulence

Organized by Lin Fu and Feng Xiao

MS0724 - Non-Newtonian fluid flows: Numerical schemes and computational simulations

Organized by Hirofumi Notsu and Cassio M. Oishi

MS0725 - Towards Next-Generation Aircraft Design with High-Fidelity Simulation Technologies

Organized by Yoshiaki Abe, Keiichi Shirasu, Tomonaga Okabe and Shigeru Obayashi

MS0726 - High Performance Computing in Biomechanics

Organized by Xiao-Chuan Cai and Rongliang Chen

MS0727 - Multi-level iterative solvers for finite element systems

Organized by Matthias Mayr, Martin Kronbichler and Santiago Badia

MS0728 - Efficiency and reliability in biomedical modeling: computational and mathematical advances

Organized by Simona Perotto, Nicola Ferro and Hiroshi Suito

MS0729 - Advances in High-Order Methods for Computational Fluid Dynamics

Organized by Krzysztof Fidkowski, Per-Olof Persson, Chunlei Liang and Ngoc Cuong Nguyen

MS0730 - Structure-preserving model reduction for nonlinear systems

Organized by Boris Kramer and Yuto Miyatake

MS0731 - Advances in Rigorous and Agile Coupling of Conventional and Data-Driven Models for Heterogeneous Multi-Scale, Multi-Physics Simulations

Organized by Pavel Bochev, Paul Kuberry and Irina Tezaur

MS0732 - COMPUTATIONAL MODELLING AND EXPERIMENTAL IMAGING OF GRANULAR AND MULTIPHASE SYSTEMS: TOWARD IMPROVED VALIDATION AND SYNERGISTIC APPLICATION

Organized by Kit Windows-yule and Jonathan Seville

MS0733 - Advanced Numerical Methods and Related Software Development

Organized by Amane Takei, Mohamed Shadi, Gabriel Wittum and Ryuji Shioya

MS0734 - Discretization methods and software tools for the simulation of complex fractured media in computational geophysics

Organized by Patrick Zulian, Marco Favino, Maria Nestola and Rolf Krause

MS0737 - Semi-analytical numerical methods and their applications in mechanics and engineering

Organized by Zhuojia Fu, Rui Li, Leiting Dong and Xiang Liu

MS0738 - Nonlinearly Stable High-Order Methods for Partial Differential Equations

Organized by Siva Nadarajah, David Del Rey Fernández and Takanori Haga

MS0739 - Quantum Horizons for Computational Mechanics

Organized by Suvranu De, Vikram Gavini, Veera Sundararaghavan, Eiji Tsuchida and Amartya Banerjee

MS0740 - Machine learning methods for adaptive mesh refinement and finite element discretization

Organized by Brendan Keith and Maciej Paszynski

MS0741 - NUMERICAL METHODS FOR BUCKLING ANALYSIS AND DESIGN OF THIN-WALLED STRUCTURES

Organized by Peng Hao, Yujie Guo and Ke Liang

MS0742 - High-Order discretization of steady and unsteady biharmonic problems: Applications in elasticity and fluid dynamics.

Organized by Jean-Pierre Croisille, Matania Ben-Artzi and Dalia Fishelov

MS0743 - ADVANCES IN INTRUSIVE AND NON-INTRUSIVE ORDER REDUCTION TECHNIQUES FOR FLOW ANALYSIS, CONTROL AND OPTIMIZATION

Organized by Marco Fossati, Annalisa Quaini and Gianluigi Rozza

MS0744 - Multilevel Discretization of Mixed Variational Formulations

Organized by Constantin Bacuta and Hengguang Li

MS0745 - Waves: Advanced Numerical Methods and Applications

Organized by Reza Abedi, Robert Haber and Tamas Horvath

MS0747 - Accurate and Efficient Solution Remapping Strategies for Coupled Multiphysics Systems

Organized by Vijay Mahadevan and Paul Ullrich

MS0748 - Computational modeling and simulation of discontinuities

Organized by Amine Benzerga, Christian Brandl, Vincent Chiaruttini, Enrique Martinez, Ryan Sills, Ashley Spear and Aurélien Vattré

MS0751 - Boundary Element Method: Fundamentals and Applications

Organized by Toru Takahashi, Toshiro Matsumoto, Yijun Liu, Hitoshi Yoshikawa, Takahiro Saitoh, Hiroshi Isakari and Kazuki Niino

800 - VERIFICATION AND VALIDATION, UNCERTAINTY EVALUATION AND ERROR ESTIMATION

MS0801 - DATA-DRIVEN, SURROGATE, PHYSICS-INFORMED AND GREY-BOX MODELLING FOR TREATING RANDOMNESS AND IMPRECISION IN COMPUTATIONAL ENGINEERING

Organized by Matthias Faes, Stefano Marelli, Jean-Marc Bourinet and Enrico Zio

MS0802 - COPING WITH RANDOMNESS AND IMPRECISION IN COMPUTATIONAL MECHANICS

Organized by Matthias Faes, Pengfei Wei, Xiukai Yuan, Jingwen Song, Marcos Valdebenito and Michael Beer

MS0803 - Quality of model prognosis - from lab data to structural performance

Organized by Jörg F. Unger, Steffen Freitag, Daniel Straub, Bruno Sudret, Francisco Chinesta, Michael Beer and Phaedon-Stelios Koutsourelakis

MS0804 - Physics-Based Data-Driven Modeling and Uncertainty Quantification in Computational Materials Science and Engineering

Organized by Johann Guilleminot, Michael Shields, Lori Graham-Brady and Kirubel Teferra

MS0805 - Certification of Computer Simulations and Adaptive Modeling

Organized by Serge Prudhomme, Ludovic Chamoin, Jens Lang, Fredrick Larsson and Juan José Rédenas García

MS0806 - Verification techniques in computational physics and applied mathematics

Organized by Brian Freno and Luís Eça

MS0807 - Numerical Analysis and Design with Polymoric Uncertainties - Advanced Methods and Strategies

Organized by Michael Kaliske, Wolfgang Graf, Sigrid Leyendecker and Stefanie Reese

MS0808 - Numerical methods for verification, validation and uncertainty quantification in manufacturing, civil engineering, advanced materials and biomechanics

Organized by Naoki Takano, Kazumi Matsui, Heoung-Jae Chun, Vittorio Sansalone, Tetsuya Matsuda and Shuji Moriguchi

MS0809 - Uncertainty Quantification in Particle-Based Simulations of Fluids, Polymers, and Soft Matter

Organized by Gerald Wang

900 - STRUCTURAL MECHANICS, DYNAMICS AND ENGINEERING

MS0902 - Modelling of Structural Instability, Structural Collapse and Impact

Organized by José Santelli

MS0903 - Vehicle Scanning Method for Bridges

Organized by Yeong-bin Yang, Jong-Dar Yau, Judy P. Yang and Zhilu Wang

MS0904 - Shell and spatial structures

Organized by Francesco Marmo, Stefano Gabriele, Amedeo Manuello Bertetto and Andrea Micheletti

MS0905 - Digital twins for the design and optimisation of lightweight structures

Organized by Carol Featherston, David Kennedy, Zhangming Wu and Abhishek Kundu

MS0906 - New numerical methods for slender bodies and their interactions

Organized by Ignacio Romero, Christoph Meier, Joaquim Linn and Bastian Oesterle

MS0907 - Multiscale mechanics of soft networks: from nonwovens to polymers and living tissues.

Organized by Franck Vernerey, Nikolaos Bouklas and Catalin Picu

MS0908 - NON-MATERIAL MODELLING OF AXIALLY MOVING CONTINUA: ARBITRARY LAGRANGIAN-EULERIAN DESCRIPTION IN STRUCTURAL MECHANICS

Organized by Yury Vetyukov, Alexander Humer and Josef Kiendl

MS0909 - New Advances in Computational Modelling and Seismic Intervention Techniques of Historical Masonry Structures

Organized by Francesco Clementi, Antonio Formisano and Gabriele Milani

MS0910 - Adaptive Engineering Structures

Organized by Malte von Scheven, Manfred Bischoff, Michael Böhm, Oliver Sawodny and Lucio Blandini

MS0911 - Digital Twins and Uncertainty Quantification in Structural Dynamics

Organized by Thiago Ritto, Anas Batou, David Barton and David Wagg

MS0912 - Guided Wave-Based Structural Condition Assessment

Organized by Eleni Chatzi, Konstantinos Agathos, Rohan Soman and Wieslaw Ostachowicz

MS0913 - Recent advances in semi-analytical approaches related to moving load problems

Organized by Zuzana Dimitrovová and Piotr Koziol

MS0914 - MODELING AND SIMULATION OF FUNCTIONALLY GRADED AND MULTIFUNCTIONAL MATERIALS STRUCTURES

Organized by Justin Murin, Stephan Kugler and Vladimir Kutis

MS0915 - Finite element time-history analysis of structural systems and contents subjected to dynamic actions and interactions

Organized by Gloria Terenzi and Stefano Sorace

MS0916 - Data-Driven Computational Methods and Model Order Reduction for Structures, Structural Dynamics, and Aeroelasticity

Organized by Haeseong Cho and Sang-Joon Shin

MS0917 - Origami engineering aided by computational mechanics

Organized by Ichiro Hagiwara and Arzu Sorguç

MS0918 - Dynamic performance of ceramic composites and composite structures

Organized by Eligiusz Postek and Tomasz Sadowski

MS0920 - Statics and Dynamics of Composite Structures and Metamaterials

Organized by Jarosław Latalski, Alireza Ture Savadkoohi and Daniele Zulli

MS0921 - Advanced structural mechanics of smart and adaptive structures

Organized by Rao B.N. and Ayan Haldar

MS0922 - Advanced computational methods for wave analysis and their application

Organized by Sohichi HIROSE, Takahiro SAITOH, Taizo MARUYAMA, Zhenghua Qian and Bing Wang

MS0923 - Modeling of Damping

Organized by Chin-long Lee and Athol Carr

MS0924 - Structural Instability in Earthquake Engineering

Organized by Tung-Yu Wu, Omar Sediek and Hsiao-Hui Hung

MS0927 - RECENT ADVANCES IN RAILWAY DYNAMICS NUMERICAL MODELLING

Organized by Santiago Gregori and Stefano Bruni

MS0929 - Nonlinear computational structural dynamics in rotating turbomachinery

Organized by Evangéline Capiez-lernout, Christian Soize, Christophe Desceliers and Marc Mignolet

MS0931 - Advances of Vehicle-Bridge Interaction Dynamics

Organized by Jong-Dar Yau

1000 - MANUFACTURING AND MATERIALS PROCESSING

MS1001 - Modeling and Simulation for Additive Manufacturing

Organized by Albert To, Yuichiro Koizumi, Andreas Lundback, Stefan Kollmannsberger, Akihiro Takezawa, Ferdinando Auricchio, Massimo Carraturo, Simone Morganti and Mamzi Afrasiabi

MS1003 - Modeling, Simulation and Optimization of Functional Materials and Advanced Manufacturing

Organized by Mahdi Bodaghi, Frederic Demoly, Giulia Scalet, Oliver Weeger and Ali Zolfagharian

MS1004 - Additive Manufacturing of Polymers - Towards the Digital Twin

Organized by Dominic Soldner, Katrin Wudy and Julia Mergheim

MS1005 - Shape Optimization for Large-Scale Problems

Organized by Long Chen, Nicolas R. Gauger and Kai-Uwe Bletzinger

MS1007 - MODELING AND SIMULATION APPROACHES OF METAL ADDITIVE MANUFACTURING ON PART-SCALE

Organized by Christoph Meier, Michele Chiumenti, Neil E. Hodge, Miguel Cervera and Wolfgang A. Wall

MS1010 - MANUFACTURING PROCESS MODELING AND THE EFFECTS OF MANUFACTURING ON THE MECHANICAL PERFORMANCE OF COMPOSITES

Organized by Patrick De Luca, Anaïs BARASINSKI, Kiyoshi UZAWA and Anthony WAAS

1100 - ATOMISTIC, NANO AND MICRO MECHANICS OF MATERIALS

MS1101 - Multiscale Modeling for Materials

Organized by YUCHIEH LO, I-Ling Chang and Chang-Wei Huang

MS1102 - Computational Nanomechanics and Nanoscale Thermal Transport

Organized by Haifei Zhan, Gang Zhang and Yuantong Gu

MS1103 - Composites, Bio-composites and Nanocomposites

Organized by Jia-Lin Tsai and Jia-Yang Juang

MS1104 - Deformation Analysis of Carbon Nanomaterial with Lattice Defects

Organized by Yi-Lun Liu, Jin-Xing Shi and Xiao-Wen Lei

MS1105 - Modeling and Simulation of Materials under Harsh Environments

Organized by Keonwook Kang, Byeongchan Lee, Seunghwa Ryu and Akiyuki TAKAHASHI

MS1106 - Nanomechanics of defects in crystalline materials

Organized by Tomotsugu Shimokawa, Takahiro Shimada, Ryosuke Matsumoto and Hajime Kimizuka

MS1107 - Modeling Mechanics of Materials with Voids

Organized by Matthew Lewis and Gary Gladysz

MS1108 - Topological Defects in Mechanics, Mathematics, Physics, and Beyond

Organized by Gerald Wang, Amit Acharya and Franziska Weber

MS1110 - Frontier in nano-scale graphene and AI-assisted design of graphene-like architect materials

Organized by Zhao Qin and Chi-Hua Yu

1200 - MODELING AND ANALYSIS OF REAL WORLD AND INDUSTRY APPLICATIONS

MS1201 - NON-CONVENTIONAL METHODS FOR SOLID AND FLUID MECHANICS (NMSFM)

Organized by Wojciech Sumelka, Tomasz Blaszczyk, Hongguang Sun, Jacek Leszczynski and Giuseppe Failla

MS1202 - MODELING METHODS, SIGNAL ALGORITHMS AND MACHINE LEARNING FOR EFFECTIVE NON-DESTRUCTIVE TESTING AND STRUCTURAL HEALTH MONITORING

Organized by Menglong Liu, Gongfa Chen and Fangsen Cui

MS1203 - Nonlocal models in computational mechanics: perspectives, challenges, and applications

Mirco Zaccariotto , Marta D'Elia , Ugo Galvanetto and Pablo Seleson

MS1204 - Combined finite-discrete element methods for multi-body dynamics and fracture mechanics

Organized by Ado Farsi

MS1205 - Real World Modeling and Simulation for the realization of Human-centered Society 5.0

Organized by Tohru Hirano and Seiichi Koshizuka

MS1206 - Condition assessment of railway infrastructures

Organized by Pedro Montenegro, Munemasa Tokunaga, Matsuoka Kodai and Diogo Ribeiro

MS1207 - Offshore Wind Power : Large Scale Modeling and Assesment for the Realization of Net-zero World

Organized by Takanori Uchida

MS1208 - Industrial Application of Particle Methods

Organized by Sunao Tokura, Massimo Galbiati, Brant Ross and Mamika Kawahara

MS1209 - Advanced Computing Technique and Artificial Intelligence for Realistic Social, Traffic and Economic Problems

Organized by Hideki Fujii, Eisuke Kita, Tomoaki Tatsukawa and Shinobu Yoshimura

MS1211 - Particle and Finite Element Models for Interaction, Simulation and Statistical Design

Organized by Masakazu Ichimiya, Nobuki Yamagata, Jeffrey Fong, Robert Rainsberger and Pedro Marcal

MS1213 - Modeling&Simulation of Terrestrial Flows (Terrestrial(Geosphere) hydrologic/hydraulic flow modeling&simulation)

Organized by Hiroyuki Tosaka, Makoto Nishigaki, Tomochika Tokunaga, Masaatsu Aichi and Tomonari Shiraishi

MS1214 - Advanced Modelling for Automotive Applications in CASE Era

Organized by Tohru Hirano, Kosho Kawahara, Masato Nishi and Maurizio MAGGIORE

MS1215 - Image Processing, Discretization, and Simulation of As-Built Geometries

Organized by Scott Roberts, Nagi Mansour and David Noble

MS1216 - Solid Mechanics of Elastomers

Organized by Hiro Tanaka and Hiroshi Kadowaki

MS1217 - Analysis of Real World and Industry Applications: emerging frontiers in CFD computing, machine learning and beyond

Organized by Eleni Koronaki, Anina Šarkić Glumac and Stéphane P.A. Bordas

MS1218 - Industrial Perspectives on Isogeometric Analysis and Design with Advanced Spline Techniques

Organized by Panagiotis Karakitsios and Vasiliki Tsotoulidi

MS1219 - Cyclic plasticity and viscoplasticity modeling for various alloys and components

Organized by Tasnim Hassan and Katsuhiko Sasaki

MS1220 - HPC application on turbulent wind over urban model represented by individual shape of buildings

Organized by Tetsuro Tamura, Yasuaki Ito and Hidenori Kawai

1300 - INVERSE PROBLEMS, OPTIMIZATION AND DESIGN

MS1301 - Computational structural design for architecture and civil engineering

Organized by Makoto Ohsaki, Sigrid Adriaenssens, Ruy Pauletti and Yohei Yokosuka

MS1302 - Model Learning and Optimization for Nonlocal and Fractional Equations

Yue Yu , Marta D'Elia and Xingjie Li

MS1303 - ANALYSIS AND DESIGN OF STRUCTURAL DYNAMICAL SYSTEMS UNDER UNCERTAIN CONDITIONS

Organized by Hector Jensen, Jianbing Cheng, Marcos Valdebenito, Ioannis Kougioumtzoglou and Dixiong Yang

MS1304 - Optimization Method and Application

Organized by Eisuke Kita, Kazuhiro Izui, Masatoshi Shimoda, Satoshi Kitayama and Masayuki Nakamura

MS1305 - New Trends in Topology Optimization

Organized by EMILIO CARLOS NELLI SILVA, Shinji Nishiwaki, Yoon Young Kim, Glaucio Paulino, Gregoire Allaire, Daniel De Leon and Renato Picelli

MS1306 - Topological Design Optimization of Structures, Machines and Materials

Organized by Gil Ho Yoon, Akihiro Takezawa and Weisheng Zhang

MS1307 - Machine Learning and Uncertainty Quantification for Materials Design

Organized by Vahid Keshavarzzadeh, Arash Noshadravan and Johann Guilleminot

MS1308 - OPTIMIZING CIVIL STRUCTURES DESIGN - HOW TO ADDRESS MULTIMATERIAL, MULTICRITERIA AND MULTIPHYSICS PROBLEMS TO REDUCE THE GLOBAL CARBON FOOTPRINT

Organized by Fabrice Gatuingt, Guillaume Hervé-Secourgeon and Tulio Honorio de Faria

MS1309 - Recent progress in topology optimization and its applications

Organized by Junji Kato, Mathias Wallin, Niels Aage, Oded Amir, Bin Niu, Liang Xia, Mingdong Zhou and Peter Dunning

MS1311 - ADVANCED APPROACHES FOR OPTIMIZATION OF COMPOSITE STRUCTURES

Organized by Elena Raponi, Simonetta Boria, Carola Doerr, Fabian Duddeck and Dirk Lukaszewicz

MS1314 - STATISTICAL INVERSE PROBLEMS AND RELATED STOCHASTIC OPTIMIZATION METHODS FOR RANDOM HETEROGENEOUS MATERIALS

Organized by Florent Pled, Christophe Desceliers and Maarten Arnst

MS1315 - Engineering Metamaterials: Rational Design and Additive Manufacturing

Organized by Zhen Luo, Yiqiang Wang and Hao Li

1400 - SOFTWARE, HIGH PERFORMANCE COMPUTING

MS1401 - PSE (Problem Solving Enviornment)

Organized by Shinji Hioki, Masami Matsumoto and Shigeo Kawata

MS1402 - Software Design and Implementation for Next-Generation Parallel Architectures

Organized by David Littlewood, Henry Tufo, Hiroshi Okuda and Reese Jones

MS1403 - Advanced HPC Methods for Eigenvalue Problems and Beyond

Organized by Ali Hashemian, David Pardo, Victor Calo, Carla Manni and Quanling Deng

MS1404 - Progress and Challenges in Extreme Scale Computing and Data

Organized by Michael Heroux, Serge Petiton and Kengo Nakajima

MS1405 - HPC-BASED SIMULATIONS AND DATA SCIENCE FOR THE WIDE INDUSTRIAL REALM: AEROSPACE, AUTOMOTIVE, BIOMEDICAL, CONSTRUCTION, HEAVY...

Organized by Makoto Tsubokura, Mariano Vázquez, Takayuki Aoki and Andreas Lintermann

MS1406 - Portable, Efficient Implementation of Finite Elements for Mechanics Applications

Organized by Kyungjoo Kim, Mauro Perego and Nathan Roberts

1500 - FLUID-STRUCTURE INTERACTION, CONTACT AND INTERFACES

MS1501 - Computational Contact Mechanics

Organized by Peter Wriggers, Michel Raous, Giorgio Zavarise and Mike Puso

MS1502 - Fluid-Structure Interaction Algorithms and Applications

Organized by Justin Kauffman, Scott Miller and John Gilbert

MS1503 - Recent Advances in Numerical Methods for Multi-Material Shock Hydrodynamics

Organized by Ketan Mittal, Nabil Atallah, Vladimir Tomov, Guglielmo Scovazzi and Robert Rieben

MS1505 - Computational Fluid-Structure Interaction and Moving Boundaries and Interfaces

Organized by Artem Korobenko, Jinhui Yan, Ming-Chen Hsu, Kenji Takizawa, Yuri Bazilevs and Tayfun Tezduyar

MS1506 - Challenges and locks for fluid-structure interaction: from vibrations to non-linear transients in industrial framework

Organized by Vincent Faucher, Olivier Jamond, Nicolas Lelong, Benoît Prabel and Maria-Adela Puscas

MS1507 - Novel Numerical Algorithms for Fluid-Structure Interaction and Optimization for Flow Energy Converter

Organized by Ming-jyh Chern, Chao-An Lin and Tzyy-Leng Horng

MS1508 - IMMERSED BOUNDARY METHOD AND ITS NOVEL APPLICATIONS

Organized by Li Wang, Fang-Bao Tian, Wei-Xi Huang, Zhengliang Liu and Yi Zhu

MS1510 - Fluid-structure Interaction, Contact and Interfaces

Organized by Peng Du, Haibao Hu, Xiaopeng Chen, Feng Ren, Xiao Huang, Luo Xie and Jun Wen

1600 - GEOMECHANICS AND NATURAL MATERIALS

MS1602 - Computational Geomechanics

Organized by Jinhyun Choo, José Andrade, Chloé Arson, Ronaldo Borja, Richard Regueiro, WaiChing Sun and Jidong Zhao

MS1603 - Computational Methods for Snow Mechanics and Engineering

Organized by Fabrizio Barpi, Gianmarco Vallero, Monica Barbero, Mauro Borri-Brunetto and Valerio De Biagi

MS1604 - Machine learning in geomechanics and geomaterials

Organized by Jianfeng Wang

MS1605 - Validation of Numerical Modeling of Soil-Structures Interaction in Liquefiable Soils

Organized by Majid Manzari and Kyohei Ueda

MS1607 - Multiscale, Multifield, and Continuum-Discontinuum Analysis in Geomechanics

Organized by Haitao Yu, Qiushi Chen, Yiming Zhang, Xueyu Geng, Ningning Zhang, Hui Wang and Yunteng Wang

MS1608 - Particle-based numerical modeling in Geotechnical engineering

Organized by Yukio Nakata, Kenichi Soga, Mingjing Jiang and Shuji Moriguchi

MS1609 - Advanced computational modelling of wood, wood-based products, and timber structures

Organized by Josef Füssl, Markus Lukacevic, Josef Eberhardsteiner and Michael Kaliske

MS1610 - Numerical methods in geomechanics

Organized by Ryosuke Uzuoka, Kazunori Fujisawa, Toshihiro Noda and Feng Zhang

MS1611 - Computational Granular Mechanics

Organized by Hongyang Cheng, Klaus Thoeni, Xue Zhang and Vanessa Magnanimo

MS1612 - Multiscale Modeling and Numerical Stress Analysis of Prestressed Rocks

Organized by Vladimir Levin, Konstantin Zingerman and Anatoly Vershinin

MS1613 - Challenges in sea ice mechanics research - experimental investigation, theroretical description and numerical simulation

Organized by Jörg Schröder, Carina Schwarz, Doru C. Lupascu, Tim Ricken, Marcello Vichi and Sebastian Skatulla

MS1614 - Recent Advances in Computational Geomechanics

Organized by Nasser Khalili, Mohammad Vahab and Babak Shahbodagh

1700 - DATA SCIENCE, MACHINE LEARNING AND ARTIFICIAL INTELLIGENCE

MS1701 - Applications of Artificial Intelligence and Machine-Learning Methods to Mechanics, Materials, Medicine, and Engineering

Organized by Shaofan Li, Vickie Shim, Ying Li, Harold Park and Shingo Urata

MS1702 - Machine Learning for Cardiac Modelling and Simulation

Organized by Simone Pezzuto, Francisco Sahli Costabal, Rolf Krause, Hermenegild Arevalo and Luca Dedé

MS1703 - Incorporating fundamental principles in innovative machine learning models of physics

Organized by Reese Jones, Ari Frankel, Cosmin Safta and Nathaniel Trask

MS1704 - Deep Learning in Computational Materials Science and Engineering

Organized by Shaoping Xiao

MS1705 - Data-driven and Machine learning Method for turbulence, Fluid Loads,and fluid-structure Interaction

Organized by GANG CHEN, WEIWEI ZHANG, HUI TANG and Richard P. Dwight

MS1706 - Decision-making in large-scale atomistic material simulations

Organized by Danny Perez and Thomas Swinburne

MS1707 - Uncertainty Quantification for Data-Intensive Inverse Problems and Machine Learning

Organized by Tan Bui-thanh and Andreas Mang

MS1708 - Machine Learning Based Design of Composite Materials and Structures

Organized by Seunghwa Ryu, Grace Gu, Shu-Wei Chang and Zhao Qin

MS1710 - Numerical Simulations and Machine Learning for Micro-Meteorology Predictions and Applications

Organized by Ryo Onishi, Kai Schneider, Tomoaki Watanabe, Shaoxiang Qian and Keigo Matsuda

MS1711 - Learning models for reliable predictions and decision making: methods and applications

Organized by Laura Mainini and Matteo Diez

MS1712 - Machine Learning and Computational Modeling for Mechanical Behavior of Materials

Organized by C-S David Chen, C.T. Wu and Nien-Ti Tsou

MS1713 - Deep and Machine Learning Methodology in the Context of Application to Computational Mechanics

Organized by Yasushi Nakabayashi, Yoshitaka Wada, Masao Ogino, Akio Miyoshi and Shinobu Yoshimura

MS1714 - Advances in scientific machine learning for high dimensional many-query problems

Thomas O'Leary-Roseberry , Peng Chen and Omar Ghattas

MS1715 - Intelligent design optimization of structural and mechanical systems

Organized by Jun Yan and Bin Niu

MS1716 - Data-driven approaches in computational solid mechanics

Organized by Pietro Carrara, Francisco Chinesta, Laura De Lorenzis, Siddhant Kumar, Pierre Ladeveze, Michael Ortiz and Stefanie Reese

ABSTRACTS

Designing Flexoelectric Metamaterials through Computational Strain Gradient Engineering

Irene Arias

Universitat Politecnica de Catalunya

It is well known that by deforming some materials (piezoelectrics) electricity can be produced. This functionality makes piezoelectrics ubiquitous in sensors, actuators, and energy harvesting systems. However, only a limited set of materials exhibit piezoelectricity, which limits many technologies. Applying a strain gradient to a dielectric, e.g. by bending, also generates electric fields due to the so-called flexoelectric effect, which conversely generates strains under applied electric field gradients. Unlike piezoelectricity, this effect is universal to all dielectrics, and hence of potential broad applicability. However, flexoelectric electromechanical transduction is significant only at sub-micron scales, where high strain-gradients develop, and for this reason this effect has only been characterized and is being applied in recent years. Unlike piezoelectricity, the interpretation of experiments and the design of functional devices exploiting flexoelectricity requires accurate solutions of coupled electromechanical high-order boundary value problems on complex geometries, since field gradients are required and we lack intuition on such problems.

In this talk, I will present a theoretical and computational framework to solve general flexoelectric boundary value problems based on an Immersed Boundary Hierarchical B-spline approach. I will discuss how these calculations allow us to conceive, quantify and optimize a new class of metamaterials and composites that constructively accumulate the flexoelectric effect of nonpiezoelectric micro-structural elements, and make it available as an apparent piezoelectric response at larger scales. These multi-scale metamaterials mobilize under homogeneous macroscopic strain substantial strain gradients (and polarization) in its non-piezoelectric constituents, and ensure a buildup of generated field in the material by their non-centrosymmetric arrangement. I will also discuss how large deformations can strongly enhance the flexoelectric effect in soft materials, and furthermore, how buckling-induced emergent geometric polarization can lead to tunable/switchable electromechanical materials, or to the mechanical self-assembly of large-area flexoelectric devices. Finally, I will discuss the connection between continuum theories of flexoelectricity and atomistic models based on electronic structure calculations.

Fracture and flow in porous media: A two-scale approach and spline-based discretisation

René de Borst[1*] and Tim Hageman[2]

[1] University of Sheffield, Department of Civil and Structural Engineering, Sir Frederick Mappin Building, Sheffield S1 3JD, UK, E-mail: r.deborst@sheffield.ac.uk,

[2] Imperial College London, Mechanics of Infrastructure Materials Group, Skempton Building, London SW7 2AZ, UK. E-mail: t.hageman@imperial.ac.uk

Key Words: *Fracture, Porous media, Multiphysics, Multiscale, Fluid transport*

Since the pioneering work of Terzaghi and Biot the flow of fluids in deforming porous media has received considerable attention. However, flow in fractured or fracturing porous media, e.g. earth or rock masses, but also human tissues, has received far less attention. Yet, the presence of damage, such as cracks, faults, and shear bands, can markedly change the flow pattern and, ultimately, the physical behavior of the mixture.

Herein, we will discuss a general model for flow in progressively fracturing porous media. The two-scale approach includes flow inside stationary and propagating traction-free and cohesive cracks. The flow inside the evolving crack is assumed to be tangentially to the crack, so as to enable a two-scale approach. At the fine scale the flow in the cavity created by the (possibly cohesive) crack is modelled using a sub-grid scale model. Since the cross-sectional dimension of the cavity is small compared to its length, the flow equations can be averaged over the width of the cavity. The resulting equations provide the momentum and mass couplings to the standard equations for a porous medium, which are assumed to hold on the macroscopic scale. Examples are given not only for fluid-saturated single-phase flows, but also for unsaturated porous media, for multi-phase flows, and for non-Newtonian fluids. An assessment of the efficacy of the multiscale methodology vis-à-vis direct simulation is provided as well.

Advanced discretisation methods are needed to model a crack, which is essentially an internal free boundary. This holds a priori since higher-order continuity of the flow field is needed to ensure preservation of local mass balance, which in turn poses strict continuity requirements on the displacement field of the solid particles in view of the sup-inf condition. Isogeometric analysis seems an ideal framework to meet these requirements. We will show examples of stationary and propagating cracks and shear bands in fluid-saturated media.

Computational Mechanics-Based Digital Twin for Model Predictive Control of Autonomous UAV Landing in Adverse Conditions

Charbel Farhat

Department of Aeronautics and Astronautics
Department of Mechanical Engineering
Institute for Computational and Mathematical Engineering
Stanford University
Durand Building, 496 Lomita Mall, Stanford
Stanford, CA 94305-4035, USA

This lecture will present a two-level, data-driven, digital twin concept for the autonomous landing of aircraft in normal and adverse conditions. The concept features a digital twin instance for model predictive control; and an innovative, real-time, digital twin prototype for fluid-structure interaction and flight dynamics to inform it. The latter digital twin is based on the linearization about a pre-designed glideslope trajectory of a high-fidelity, viscous, nonlinear computational model for flight dynamics; and its projection onto a low-dimensional approximation subspace or manifold, as appropriate, to achieve real-time performance, while maintaining accuracy. Its main purpose is to predict in real-time, during flight, the state of an aircraft and the aerodynamic forces and moments acting on it. Unlike static lookup tables or regression-based surrogate models based on steady-state wind tunnel data, the real-time digital twin prototype allows the digital twin instance for model predictive control to be informed by a truly dynamic flight model, rather than a less accurate set of steady-state aerodynamic force and moment data points. The lecture will cover the fundamental aspects underlying the construction of the two-level digital twin concept and its verification by numerical simulation. Most importantly, it will also report on its preliminary flight validation in autonomous mode for an off-the-shelf unmanned aerial vehicle instrumented at Stanford University by Marco Pavone and Joe Lorenzetti.

From Engineered Metastructures to Natural Seismic Metamaterials: Theory, Computational Aspects and Experiments

C.W. Lim

Department of Architecture and Civil Engineering, City University of Hong Kong, Kowloon, Hong Kong SAR, P.R. China

Key Words: *acoustic metamaterial, bandgap, forestation, Rayleigh wave, seismic metamaterial*

The recent surge in the number of studies on seismic metamaterials is testimony to the fact that the concept of photonic crystals, phononic crystals and acoustic metamaterials [1-3] is no longer limited to basic theories and dynamic characteristics. Apart from the peculiar observation including negative stiffness, negative mass density negative refraction properties, etc., auxetic metamaterials that govern negative Poisson's ratio, nonreciprocal wave phenomena, origami/kirigami effects also find potential applications in geophysics and earthquake engineering [4-5]. Except man-made synthetic resonators/metastructures, recently forest trees at geophysical scale are reported as naturally available seismic metamaterials with capability to mitigate ground born ambient vibrations and incoming seismic waves at subwavelength frequency region. The work to be presented here elaborates a class of materials and structures ranging from engineered phononic crystals and acoustic metamaterials in Fig (a,b) to natural seismic metamaterials in Fig. (c,d) that show exotic yet with outstanding application potentials. Besides discussing the peculiar yet wonderful wave propagation characteristics of periodic structures for wave active control, topological protected interface modes, etc., the exciting wave dispersion response that found applications for manipulation Rayleigh wave and possible forestation as a means for geographical regional isolation against ground surface wave motion will also be presented.

Development of New Rocket Propulsion System "Rotating Detonation Engine"

Akiko Matsuo

Department of Mechanical Engineering, Keio University
3-14-1 Hiyoshi, Kohoku-ku Yokohama, Japan
matsuo@mech.keio.ac.jp

Key Words: *Detonation, Rotating Detonation Engine, CFD, Chemical Reaction*

Detonation wave, you may not be familiar with. It is a combustion wave propagating at supersonic speeds, and so there is a preceding shock wave in front of the exothermic reaction zone. In recent decades, detonation has attracted attention for use of a new type of aerospace propulsion engine so called “detonation engine”, since the detonation engine has higher theoretical thermal efficiency than the conventional rocket engine. Our research group, in collaboration with Nagoya University, has successfully demonstrated the world’s first space flight of detonation engines on July 27, 2021 [1].

We are working numerically to elucidate the fundamentals for detonation combustion and to predict the performance of the designed combustor geometry of “Rotating Detonation Engine (RDE)”, which is one of detonation engines, by solving the compressible flow with chemical reactions.

For RDE, there are some problems to be solved such as continuity and heat load. Here, we focus on two topics. On is the ozone addition to the hydrogen oxygen premixed gas to improve its characteristics for detonation engine, and the other is the investigation of newly designed combustors, such as side wall injections and diverging combustor geometry [2].

The ozone sensitization due to the O radical produced via ozone thermal decomposition is attracting attention as a mean of improving the detonation stability and extending its limits. Our numerical results show that the ozone can be expected to help to the complete the combustion faster and improve the thermal efficiency.

A series of numerical simulations predict the thrust performance by changing the geometrical parameters of length and shape of RDE combustor and the injector configuration, and the simulation results indicate the appropriate design of RDE. RDE is the new type of aerospace propulsion engine, and its optimal combustor shape and configuration is not clarified yet. Therefore, based on our numerical results, we will propose new combustor geometry to improve the stability and performance.

Key Words: *Patient-Specific Simulation, Cerebral Circulation, Revascularization, Multimodal Medical Image, Machine Learning*

Cardiovascular disease such as heart disease or stroke is one of main causes of death in the world. A patient-specific simulation has been widely used not only for scientific study to elucidate mechanism between hemodynamics and cardiovascular diseases but also for clinical applications to predict blood flow after surgery. Since carotid artery stenosis is a major risk factor for a stroke, patients with severe carotid artery stenosis often undergo revascularization surgery such as carotid artery stenting to prevent a future stroke. Predicting the blood flow in the brain after the surgery is very important to determine the most suitable surgery for the patients,

The surgery affects the blood flow in the brain as well as in the entire circulatory system. In order to reflect the patient's conditions in the multi-scale cardiovascular simulation, geometric and physiological parameters derived from clinical data are applied to the region of interest with the literature data for the rest of circulatory system[1]. Thus, quantifying the impact of uncertainties in the data on simulated quantities is an essential task to obtain reliable results. However, uncertainty quantification is time-consuming and computationally expensive for routine clinical diagnosis. The authors have been developing a data-driven surrogate model using machine learning technique and applied the model for risk assessment of a cerebral hyperperfusion condition, which is one of complications after revascularization of stenosis in the carotid artery[3]. In the plenary lecture, the recent advances in the multi-scale cardiovascular simulation will be presented as well as a future perspective of machine learning in the patient-specific simulation for clinical applications.

Deep Materials Modeling and Design

Chuin-Shan (David) Chen

Department of Civil Engineering, Department of Materials Science and Engineering, National Taiwan University, No. 1, Sec. 4, Roosevelt Rd., Taipei 10617, Taiwan, dchen@ntu.edu.tw, https://cschen.caece.net

Key Words: *Materials Modeling, Materials Design, Deep Learning, Composite, Metals, Bioinspired Materials*

Materials modeling and design play a central role in mechanical applications. In this talk, I will present our three ongoing efforts using deep learning techniques to advance our materials modeling and design capability. The first is on generalizing a deep material network (DMN) to capture microstructural features using a graph neural network (GNN). We link microstructural features of RVEs to microstructural descriptors of DMN by introducing GNN into DMN architecture. A microstructure's topologies and features are utilized as input data for GNN. Through a series of message passing processes of GNN from the input, the extracted embedding vector from the microstructure can be used to find the correlations between microstructural descriptors of DMN, which correspond to different RVEs, through an end-to-end offline training process of GNN-DMN network architecture. Once the network is trained, it can be viewed as a unified composite material modeling for RVEs with similar morphologies and be utilized for online predictions of material nonlinear behaviors due to the inherent merits of DMN. The effectiveness and efficacy are demonstrated for two-dimensional two-phase composite materials with different morphologies, including matrix-inclusion, amorphous and anisotropic geometries. The second part of my talk is on developing a surrogate model for crystal plasticity using GNN and recurrent neural network (RNN). To enhance the accuracy of spatial-temporal prediction, we introduce an independent self-weight for message passing in the GNN layer to distinguish the message from the grain itself and those from the neighboring grains. Strain incompatibility is integrated into the loss function as a physics-informed regularization term. The proposed deep learning model is trained on the dataset generated by a high-fidelity crystal plasticity simulation to predict the stress-strain response and microstructural evolution under complex loading paths. The accuracy of the surrogate model on spatial-temporal prediction is shown to be significantly improved. We also demonstrate the generalizability of the proposed surrogate model on various polycrystalline geometries. The third part of my talk is on designing bioinspired microstructures with target properties. Distinct from engineering materials, biological structural materials are often composites of hard/brittle minerals and soft/ductile proteins arranged into complex microstructures with remarkable mechanical properties. A property-prediction model for bioinspired microstructures using supervised learning and a framework for designing bioinspired structural materials with tailored mechanical properties using reinforcement learning will be addressed.

Empowering data-informed engineering from smarter data, sensing and hybrid modelling

Francisco Chinesta[1*], Elias Cueto[2]

[1] Arts et Metiers Institute of Technology, Paris, France, Francisco.Chinesta@ensam.eu
[2] I3A, Universidad de Zaragoza, Spain, ecueto@unizar.es

Key Words: *Model Order Reduction, Active Learning, Data-Driven modelling, Twins*

Data has not an intrinsic nature, data exist with respect to a specific mission, the one of performing diagnosis, or the one of enabling the construction of a model able to make efficient (fast and accurate) prognosis, and the subsequent prescriptive actions and decisions.

In engineering data is expensive in what concerns its collection, transmission, storage and analytics. For this reason, collecting the right data, at the right place and instant is preferred. Active learning constitutes a timely research topic, and more importantly, physics-aware active learning can profit of the existing knowledge, in conjunction with the previous collected data, for driven the data acquisition.

With the data available, machine learning can proceed for extracting a model relating the input-data with the output-data. However, when the amount of data is small, frugal AI and frugal machine learning techniques must be considered. For reducing the data needs, physics informed (from the physics-based model or from the thermodynamical consistency), data-augmentation, data reduction (auto-encoders), reinforced learning, transfer learning (augmented learning), … allow defining efficient (fast and accurate) learning technologies.

Now; that models are available, engineering can profit: Data-assimilation, monitoring, diagnosis, prognosis, prescriptive control and decision making, can operate, in a supervised or unsupervised manner, profiting of the advanced visualization technologies: virtual, augmented and hybrid reality, for creating a physics-aware digital twin, also called Hybrid Twin for emphasizing the two coexisting modelling frameworks: the physics-based (operating in real-time thanks to the use of advanced model order reduction techniques, as for example the so-called PGD) and the data-driven models (as just indicated physics informed).

Machine-Learning based Computational mechanics as a powerful tool for engineering and science

YuanTong Gu[1*], Jinshuai Bai[1] and Hyogu Jeong[1]

[1] School of Mechanical, Medical and Process Engineering, Queensland University of Technology, Brisbane, QLD 4000, Australia, yuantong gu@qut.edu.au

Key Words: *Physics-Informed Neural Network, Machine Learning, Computational mechanics*

Nowadays, the Physics-Informed Neural Network (PINN)-based computational solid mechanics is being rapidly developed, although it is currently still in its infant stage. It has been becoming a game-changer for computer modelling and simulation for engineering and science.

Firstly, this talk will review the most recent developments of PIINN for mechanics, including solid mechanics, fracture machines and fluid mechanics. The main challenges in application of PINN to computational mechanics are discussed.

Second, in PINN, the loss function plays a critical role. It is still an opening question for developing an effective, robust, and general loss function for solid mechanics problems, although a couple of approaches, for example, the energy-based loss function and the collocation loss function, have been proposed to create the loss function. We proposed a new way to formulate the loss function based on the Least Squares Weighted Residual (LSWR) method for PINN-based computational solid mechanics. Using the LSWR method, the proposed loss function is tailored to a dimensionless form, and only one parameter is required to be determined based on the spacing of the sample points. It has been proved that the proposed LSWR loss function is effective, robust and accurate for both the displacement and stress fields. Meanwhile, the effectiveness of the proposed LSWR loss function can be easily extended to for geometric nonlinearity problems with transfer learning. The proposed LSWR loss function provides an effective way for PINN based computational solid mechanics and is straightforward to be implemented

Third, the recent research in the speaker's group on PINN will also be reported in this talk. It has proven that physics-informed machine learning will be the new generation of a computer modelling framework for mechanics.

Discrete Crack Models in Regularized Fracture Mechanics for Mesh-based and Mesh-free Methods

Michael Kaliske[1*], Johannes Storm[1]

[1] Technische Universität Dresden, Institute for Structural Analysis, 01062 Dresden, Germany, Michael.Kaliske@tu-dresden.de, https://tu-dresden.de/bu/bauingenieurwesen/sdt

Key Words: *Representative Crack Element (RCE), Phase-field Fracture, Eigenfracture*

The explicit representation of cracks in discretised models via domain bounds, the mesh, or special ansatz functions is the most direct way to model fracture and common use in computational mechanics with field discontinuities. In addition, pure continuous models are frequently applied to the simulation of weak and strong discontinuities, for instance nonlocal plasticity and nonlocal damage formulations. The latter models gain more flexibility for the numerical discretisation and introduce a length-scale parameter for the description of the fracture process or localisation zone.

Investigations on the energetical balance during fracture dates back to the contributions of GRIFFITH and IRWIN, and has yielded later a fully variational formulation, the *free-discontinuity problem* [1], where the displacement field as well as the location of displacement discontinuities are unknown a priori. Regularised formulations of the free-discontinuity problem like the *phase-field method for fracture* [2] and the *eigenfracture* approach [3] have gained much attraction because they combine precision of discrete and flexibility of continuous approaches to fracture mechanics.

In the focus of this talk is the additive decomposition of the spatial derivative of the displacement field in the presence of a crack into an absolutely continuous part and a jump part, which is shown via the space of special functions of bounded variations [1]. The former part describes the deformation of the bulk material at the crack surface, whereas the latter part focuses the contribution of crack opening. However, continuous fracture models calculate the overall derivative of the displacement field and do not provide this decomposition, which is necessary for a precise description of the bulk material and processes inside the crack gap. In order to overcome approximatively decompositions via artificial split models, the framework of *Representative Crack Elements* is developed, solving the decomposition as a variational problem.

Illustrative applications to elastic and inelastic bulk materials, to crack surface friction and finite deformations, as well as to multi-physical problems are used to compare to experimental observations and numerical results from discrete fracture models. Simulations are performed by means of the phase-field approach and the eigenfracture method using the mesh-based *Finite Element Method* and the mesh-free *Material Point Method*.

Opportunities for Machine Learning in Computational Mechanics

Ellen Kuhl

Stanford University, Stanford, CA, 94305, USA, ekuhl@stanford.edu

Key Words: *Neural Networks, Bayesian Inference, Bayesian Physics-Informed Neural Networks*

Understanding real-world dynamical phenomena remains a challenging task. Across various scientific disciplines, machine learning has advanced as the go-to technology to analyze nonlinear dynamical systems, identify patterns in big data, and make decisions around them[1]. Here we systematically compare two families of machine learning tools and illustrate their applications in computational mechanics: neural networks and Bayesian inference[2].

Neural networks minimize a loss function to optimize the network parameters, without any prior knowledge of the underlying physics. Physics informed neural networks expand the loss function by an additional physics term and also optimize for physics parameters. In addition to plain neural networks, physics informed neural networks not only interpolate the training data well, but also extrapolate and predict future behavior. We illustrate the features of physics informed neural networks for several biomedical applications[3].

Bayesian inference maximizes a prior-weighted likelihood function to estimate posterior distributions of model parameters. It can be combined with plain neural networks or physics informed neural networks to ignore or integrate the underlying physics. Bayesian inference not only infers model parameters to fit the training data, but also provides credible intervals to quantify the quality of the model. We illustrate the potential of Bayesian inference for dynamical systems in the life sciences[4].

We conclude by discussing the inherent advantages and disadvantages of neural networks, Bayesian inference, and a combination of both to provide guidelines which approach to select. We anticipate that our study generalizes to a wide variety of nonlinear dynamical systems and opens new opportunities for machine learning in computational mechanics.

On law- and data-based methods

G. R. Liu[1*]

[1] Department of Aerospace Engineering and Engineering Mechanics,
University of Cincinnati, Cincinnati, OH 45221-0070, USA
liugr@uc.edu (http://www.ase.uc.edu/~liugr/)

Key Words: *Finite Element Method, Smoothed Finite Element Method, Machine Learning, Artificial Intelligence, numerical methods, computational methods*

Machine learning methods [1], such as the Artificial Neural Networks (ANNs), have been applied to solve various science and engineering problems. TrumpetNets and TubeNets were recently proposed by the author [2][3] for creating two-way deepnets using the standard finite element method (FEM) [4] and S-FEM [5][6]as trainers. The significance of these specially configured ANNs is that the solutions to inverse problems have been, for the first time, analytically derived in explicit formulae. Such advancements have shown that fundamental understanding on physics law-based and data-based methods has found critical for development of novel methods for various types of engineering problems [9][10][12].

This paper discusses general issues related to law-based [4]-[8] and data-based [1][3] methods, including the principle, procedure, predictability, and property of these two types of methods in dealing with different types of problems. We present also a novel neural element method (NEM) [9][10] as a typical example of a possible combination of these two types of methods. The key idea in NEM is to use artificial neurons to form elemental units called neural-pulse-units (NPUs), using which shape functions can then be constructed, and used in the standard weak and weakened-weak (W2) formulations to establish discrete stiffness matrices, similar to the standard FEM. Detailed theory, formulation and codes in Python and numerical examples are presented to demonstrate this NEM. For the first time, we have made a clear connection, (in theory, formulation, and coding), between ANN methods and physical-law-based computational methods. We believe that his novel NEM changes fundamentally the way approaching mechanics problems, and opens a possible new window of opportunity for a range of applications. It offers a new direction of research on un-conventional computational methods. It may also have an impact on how the well-established weak and W2 formulations can be introduced to machining learning processes, for example, creating well-behaved loss functions with preferable convexity.

A semi-resolved CFD-DEM approach for particulate flows with thermal convection

M. B. Liu[1*], Z. K. Wang[1]

[1] College of Engineering, Peking University, Beijing 100187, China, Email: mbliu@pku.edu.cn

Key Words: *Particulate flows, CFD-DEM, Semi-resolved CFD-DEM, Thermal convection*

Particulate flow has a wide range of industrial applications and is frequently modeled with coupled CFD-DEM approaches. In this work, we first identified a simulation gap between the resolved CFD-DEM and unresolved CFD-DEM through a size effect study. We then analyzed the error sources of the conventional unresolved CFD-DEM when modeling particulate flows with comparable mesh size and particle diameter. We finally developed a semi-resolved CFD-DEM model[1, 2], which combines the advantages of both resolved and unresolved CFD-DEM models. The semi-resolved CFD-DEM uses a drag force model to characterize particle-fluid interaction, while the relative velocity in the drag force model is corrected through kernel-based approximations on the neighboring fluid cells rather than simply taking values in the local cell containing the concerned particle, and the void fraction in the force model is corrected as well. A number of numerical simulations including the sedimentation of single particle, separation of particles in a fluidized bed, spouted bed with heat particles, particulate flows in complex porous media, additive manufacturing (selective laser melting and direct laser deposition) have been conducted. Numerical results from different CFD-DEM approaches are compared together with experimental data. It is shown that the presented semi-resolved CFD-DEM bridges the simulation gap between the resolved CFD-DEM and unresolved CFD-DEM while it is as efficient as the conventional unresolved CFD-DEM and as accurate as the resolved CFD-DEM.

Hierarchical Deep Learning Neural Network (HiDeNN)-FEM- AI for process design and performance prediction of material systems

Wing Kam Liu, Walter P. Murphy Professor and Co-Founder of HIDENN-AI, LLC

Northwestern University (w-liu@northwestern.edu)

We propose a mechanistic Artificial Intelligence (AI) framework, called Hierarchical Deep Learning Neural Networks or HiDeNN-AI [1,2,7,8] for discovering the multiscale linkage of process-structure-property of additive manufacturing systems. The HiDeNN-AI discovery has three sequentially executed steps: (1) using available data to characterize an unknown physical process in manufacturing, (2) enriching the database and training with mechanistic knowledge coming from the system identification in step (1) with uncertain parameters to create a reduced order model with uncertainty, and (3) using the reduced order model to generate sufficient data to discover new robust mathematical principles that are able to (a) perform predictive solutions for design and optimization, and (b) provide simple relationship for online monitoring and control. We have applied this HiDeNN-AI framework to address the Air Force Research Lab (AFRL) AM modeling challenges [3, 4, 5]; and for the prediction of the as-built mechanical properties [6]. To further enhance HiDeNN-AI, a reduced-order modeling method accounting input uncertainty, called the Tensor Decomposition (TD) [7], is being developed. The so-called HiDeNN-AI-TD is expected to solve the general engineering design and manufacturing problems in high dimensional space-time-parametric domains at deep discount in computational cost. Once the offline database is set up, the mechanistic machine learning module of HiDeNN-AI can be activated for process design, real time system monitoring and control or the identification of key processing parameters for the desired performance of the manufactured material systems with uncertainty quantification. Various results comparing the HiDeNN-AI-TD approach with the conventional machine learning models will be shown using real-time IR in-situ measurement, and high-frequency thermal signatures for the predictions of mechanical properties and the detection of lack of fusion and keyhole porosities. Similar applications to polymer matrix composites will be presented.

Recent Advances of Constitutive Models of Soft Smart Materials - From Molecular, Network Scales to Continuum Scale

Zishun Liu[1*]

[1] International Center for Applied Mechanics,
State Key Laboratory for Strength and Vibration of Mechanical Structures,
Xi'an Jiaotong University, Xi'an, 710049, China, zishunliu@mail.xjtu.edu.cn)

Key Words: *Constitutive model, Hydrogel, Molecular Dynamics, fracture of hydrogels*

Hydrogel is a type of synthetic polymers composed of cross-linked polymer network and water. A polymer network can imbibe copious amounts of water and swell, which can be used in many potential applications, such as stretchable conductors, tissue engineering and fire resistance materials. Before these applications, hydrogels should be studied carefully. We have studied the mechanical and thermal properties of hydrogels from the molecular scale to the continuum scale. In this presentation, the multi-scale study of hydrogels will be discussed. Such as the ab-initio simulations are carried out to investigate the force field parameters of hydrogel and the randomly crosslinked molecular structure of hydrogel is built by simulating the reaction process of monomer and crosslinker. The diffusion property of solvent molecules and heat conduction in hydrogels with different water contents are simulated by using Molecular Dynamics method. Besides, the swelling, mechanical, as well as the phase transition behaviours of environmental sensitive hydrogels (such as pH sensitive, thermal sensitive and photosensitive) are investigated by continuum theory and FEM approach. As current constitutive theories face challenges when predicting the extremely large deformation and fracture of hydrogels, and in order to reveal the fundamental mechanism of the various mechanical behaviours of hydrogels from bottom up, we also proposed a proper hydrogel network model to provide a better approach to bridge the gap between the micro-structure and the macroscopic mechanical responses. This presentation will summarizes the theoretical and numerical researches on the different hydrogel models, aiming to provide new insights into the effect of microstructure on the swelling-deswelling process, hyperelasticity, viscoelasticity and fracture of hydrogels. In order to verify the proposed constitutive models, we have carried out some experimental studies. Furthermore, some interesting experimental results will be presented in this talk also.

Wings at low Reynolds numbers and lifting line theory

Jawahar Sivabharathy Samuthira Pandi[1] and Sanjay Mittal[2*]

[1] PhD Student, Indian Institute of Technology Kanpur, jawahar@iitk.ac.in
[2] Professor, Indian Institute of Technology Kanpur, smittal@iitk.ac.in

Key Words: *Mode C instability, Hairpins, Laminar separation bubble, Wing-tip vortex, Cellular shedding, Streamwise vortices*

Low Reynolds number flows past UAVs, MAVs and drones have gained significant interest because of their surveillance, communication, weather monitoring, etc. We first study the transition of flow past an end-to-end wing [1]. The flow becomes unsteady beyond Re=600 approximately via the primary instability of the wake leading to vortex shedding. Three-dimensionality sets in at Re~1280.9 via mode C instability and hairpin vortices. The spatio-temporal structure of the flow is examined via spanwise variation of lift coefficient. Interaction of the shear layer vortices with the separated boundary layer leads to formation of a Laminar Separation Bubble (LSB) at Re~20,000, causing a delay in flow separation. The airfoil experiences a very significant increase in lift and decrease in drag. The primary mechanism of formation of LSB is found to be two-dimensional. Unlike the frequency of vortex shedding, the frequency of shear layer vortices experiences a sharp change at the onset of LSB.

The main objective of the work is to study the effect of wing-tip vortices on the transition of flow on a finite wing and its aerodynamics at low Reynolds numbers. Numerical simulations for flow past a finite rectangular wing with NACA 0012 section at Re=1000 for various semi-aspect ratios ($0.25 \le sAR \le 7.5$) over a range of angle of attack ($0° \le \alpha \le 14°$) reveal streamwise vortices, which increase in strength and number to occupy an increasing spanwise extent with increase in α. Unlike the prediction from the Lifting Line Theory (LLT) by Prandtl [2], they result in non-monotonic spanwise variation of local force coefficients for $\alpha > 8°$. Viscous and pressure drag dominate for low- and high-sAR respectively. The time-averaged drag coefficient first decreases and then increases with increase in sAR. This is in contrast to the prediction from LLT and will be discussed in detail in the presentation. Vortex shedding, for $\alpha = 14°$, is single cell and parallel for $sAR < 3$. Shedding is in two cells with oblique angle that varies with time, leading to large spanwise variation in rms of local force coefficients for higher sAR. Various type of dislocations, reported earlier in wakes of bluff bodies [3], are seen for different α and sAR. Dislocations, for $\alpha = 14°$, appear at same spanwise location for sAR=3 and at different spanwise locations for $sAR \ge 4$. Vortex shedding for $\alpha = 14°$ and sAR=5 exhibits one cell structure in the near- and two-cell in the far-wake due to splitting and reconnection of vortices near midspan in the moderate wake. Linkages form between counter rotating spanwise vortices for $sAR \ge 1$. Additional linkages between shed- and wing-tip vortices are observed for lower sAR. The strength of wing-tip vortex increases with α. At each α, the strength and radius of its core, estimated using a forced-free vortex model, increases up to a certain sAR beyond which it is approximately constant. The incompressible flow equations are solved via a stabilized finite element method [4].

Isogeometric Analysis: Some recent advances and applications

Alessandro Reali[1*]

[1] University of Pavia, Dept. of Civil Engineering and Architecture, alereali@unipv.it, http://www.unipv.it/alereali

Key Words: *Isogeometric Analysis, Coupled Problems, Phase-field Modeling*

Isogeometric Analysis (IGA) is a successful simulation framework originally proposed by T.J.R. Hughes et al., in 2005, with the aim of bridging Computational Mechanics and Computer Aided Design. In addition to this, thanks to the high-regularity properties of its basis functions, IGA has shown a better accuracy per degree-of-freedom and an enhanced robustness with respect to standard finite elements in many applications - ranging from solids and structures to fluids, as well as to different kinds of coupled problems - opening also the door for the approximation in primal form of higher-order partial differential equations.
After a concise introduction of the basic isogeometric concepts, this lecture aims at presenting an overview of some recent advances in IGA with a special focus on coupled problems where the characteristics of IGA seem to be of great advantage. In particular, applications that will be discussed include the simulation of fluid-structure interaction in different contexts like, e.g., biomechanical problems, studies on the effect of mechanically-induced stresses on prostate cancer growth, thermo-mechanical simulations of additive manufacturing processes, electro-mechanical simulations for biological tissues, and the use of phase-field modeling for fracture and topology optimization problems or for predicting the polarization evolution in elastic ferroelectric materials. The last part of the presentation will be finally devoted to the description of a simple, accurate, and inexpensive simulation technique for laminated structures, allowed by the peculiar IGA features.

Parametric Model Order Reduction for Fluid and Solid Objects

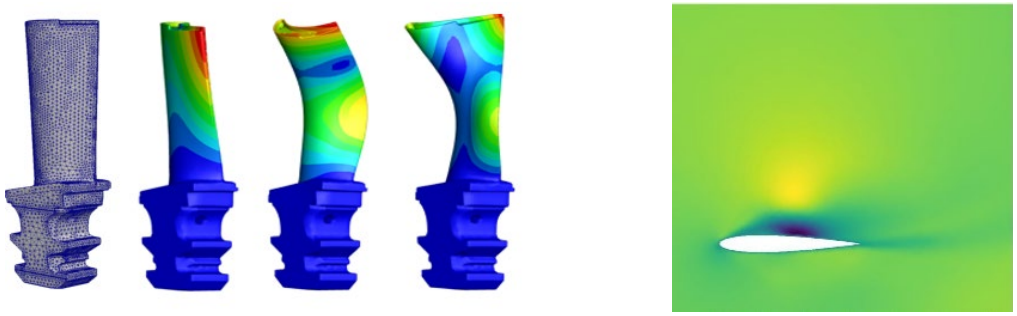
SangJoon Shin[1*]

[1] Department of Aerospace Engineering, Seoul National University, Seoul, South Korea, ssjoon@snu.ac.kr

Key Words: *Model order reduction, Multiphysics Problems, Large-size computational anaysis, Computational structural dynamics, Computational fluid dynamics*

The large-size computation conducted in the engineering field is complex, higher-dimensional, and occasionally highly nonlinear. While a variety of the direct numerical analysis have been attempted for the solid, fluid and thermal analysis, its computational burden still remains excessive. In order to reduce such computational load, approaches such as parallel computing and model order reduction have been attempted. Whilst the parallel computing may reduce the computational time significantly as the computation is performed in a distributed manner, it will not reduce memory requirements.

Instead, the model order reduction (MOR) will be considered. MOR aims to reduce the dimension of the higher-dimensional full order representation to a smaller one along with the minimal discrepancy. It will be efficient in terms of both computational speed and memory requirement. Approaches for MOR can be widely categorized into the following two categories: intrusive and non-intrusive MOR. The intrusive MOR is dependent on the governing equation while the non-intrusive MOR does not require knowledge of the governing equation. In this paper, an overview of the model order reduction and numerical results will be presented. The examples include intrusive MOR for the solid analysis [1] and non-intrusive MOR for the fluid analysis [2]. By examining such examples, efficiency and accuracy by various MOR approaches will be demonstrated.



(a) Intrusive MOR for the solid analysis[1] (b) Non-intrusive MOR for the fluid analysis[2]

A Topology Optimization approach towards fluid flow design problems

Emílio Carlos Nelli Silva[1*]

[1] Polytechnic School of the University of São Paulo, São Paulo, Brazil, 05508-010, ecnsilva@usp.br

Key Words: *Topology optimization, Fluid flow design problems*

Topology optimization (TO) is a computational engineering tool used to provide optimized geometries, with highly attractive applications in the areas of structural and fluid flow path designs. The main goal of TO is to solve a material distribution problem within a design domain considering an objective function and a set of possible constraints. In the case of fluids, the design variable values {1} and {0} usually indicate the regions of the domain where the fluid is free to flow (*fluid*) or is restricted to flow (*solid*), respectively. The use of TO for fluid problems began with laminar flows, and the current most challenging applications of TO methods for fluid flow design include the consideration of turbulent and compressibility effects. Another important aspect is the design of blood flow devices, since blood is a living fluid, subject to blood damage (hemolysis and thrombosis). Thus, this lecture will present the main aspects of TO for fluid flow design covering laminar and turbulent flows, Newtonian and non-Newtonian fluids, blood damage (hemolysis and thrombosis), and incompressible and compressible flows. The TO formulation will be presented based on the continuous design variable formulation, and also on a recent development based on discrete design variables and sequential integer linear programming. Examples include the design of fluid flow channels/devices, and flow machine rotor/volute topologies.

Prediction of fatigue crack propagation using effective regularization techniques for regression problems

Yoshitaka Wada[1*]

[1] Kindai University, 3-4-1 Kowakae, Higashiosaka, Osaka Japan,wada@mech.kindai.ac.jp

Key Words: *Fracture Mechanics, Machine Learning, Surrogate Model, Imbalanced Frequency Problem*

This study presents the capability and applicability for fatigue crack propagation evaluation using the latest machine learning. Fatigue crack propagation includes several governing laws and computation methods which are elastic stress field, stress intensity factors, Paris' law and criterion of crack propagation direction. Crack propagation phenomenon simultaneously occurs with these laws. The computation time is needed for one case of crack propagation. Many crack propagation paths for a training are computed as training data in 2-dimension using s-version finite element method, however a machine learning can easily predicted interpolated crack propagation path and its rate very shortly than a finite element analysis.

Three training levels are examined. In 1st training level, crack position vector, propagation direction vector and stress intensity factors are for input parameters. In 2nd training level, crack position vector, crack propagation direction vector, six stress components around crack tip are for input parameters. In last training level, only crack position vector and crack propagation direction vector are trained as input parameters. The last level requires only geometrical configuration to predict crack propagation. In order to simplify the problem, all of parameters are completely determined as constant values. The simulation can represent curved crack path by incremental crack propagation computations. As a result of comparisons between each level, the 1st level exhibits the highest reproducibility. If the same computation results as the 1st level, the last level requires 10 times training data and time to get convergence of the convolutional neural network system. The accuracy of all phases presents the common deviation from the correct solution. The deviation appears at the beginning of crack growth involving steep crack direction change. As a result, data augmentation is employed for the first several computation steps on each initial crack angle, and training data of cracks with fine intervals.

Interaction of two cracks propagation is predicted and evaluated so that we'd like to enhance the prediction ability of crack propagation. When two cracks are very closed and interaction occurs evidently, data augmentation also should be employed because of very close cases less than usual state as concerns with distance of two cracks. The dense distribution of the training data and the augmentation produce highly accurate prediction of crack propagation in case of very close cracks. A quality of training data largely affects an ability of a prediction. The important thing is that the training data should contain data to predict some phenomena. We'd like to discuss the results of several learning examples and show the applicability of the machine learning to the actual engineering problem with high accuracy.

Virtual elements in engineering sciences

Peter Wriggers[1*]

[1] Leibniz University Hannover, Institute of Continuum Mechanics, an der Universitaet 1, 30823 Garbsen, wriggers@ikm.uni-hanover.de (https://www.ikm.uni-hannover.de/en/wriggers/)

Key Words: *Virtual elements, fracture mechanics, contact mechanics, homogenization, Kirchhoff plates*

Virtual elements (VEM) were developed during the last decade and applied to various problems in solid mechanics. The method includes elements that can have arbitrary shape including non convex polyhedra. This flexibility with respect to the geometry can be explored and utilized within engineering applications for specific problems.

This lecture will cover several applications of the virtual element method in the area of solids mechanics which are related to

- contact and interfaces,
- fracture using classical and phase field approaches,
- homogenization of polycrystal microstructural response,
- design C1-continuous ansatz spaces for plates and gradient elasticity

For these problem classes we will discuss the pros and cons of virtual elements for efficient, reliable and robust solutions in the engineering world.

A Multiscale Computational Framework for the Simulation of Graphene Nanoplatelets

Panagiotis Gavallas[1*], Dimitrios Savvas[1] and George Stefanou[1]

[1]Aristotle University of Thessaloniki, 54124 Thessaloniki, Greece
pgavallas@civil.auth.gr, dimitriosavvas@yahoo.gr, gstefanou@civil.auth.gr

Key Words: *Graphene Nanoplatelets, Multiscale, Homogenization, Random Fields*

In this paper, a multiscale computational framework is developed for the simulation of graphene nano-platelets (GnPs) used as reinforcements in composite materials. GnPs, which consist of multiple graphene sheets connected by van der Waals forces, are modelled following the Molecular Structural Mechanics (MSM) approach [1] using energy equivalent beam and spring elements. Stone-Wales as well as single and double vacancy defects are considered in the graphene sheets [2]. The apparent mechanical properties of GnPs are described by random fields, obtained by means of computational homogenization [3]. Parametric investigations are carried out to examine the effect of the number of constituent graphene layers, as well as of defect type and density, on the mechanical properties of GnPs.

Key Words: *NiTi shape memory alloy, hydrogen diffusion, scale conversion*

NiTi shape memory alloys inevitably come into contact with hydrogen under certain service environment, which has influence on its mechanical behavior. In this work, the effect of hydrogen on the cyclic deformation of NiTi alloys is revealed experimentally and theoretically through cyclic tensile-unloading experiments of super-elastic NiTi alloy wires after hydrogen charging.

In the first cycle of the strain-stress curves, the transformation platform of loading curve is divided into two parts after ex-situ hydrogen charging of NiTi alloy wires. With the presence of hydrogen, initial stress of second transformation (the second stage of transformation platform) and the reverse transformation increases, and transformation platform is shortened. The longer the charging part is, the earlier the second transformation starts. In addition, hydrogen charging time and charging length (the length of hydrogen charging part) increase residual strain during loading ang unloading process. The reason is that hydrogen hinders transformation of NiTi alloys.

As the number of loading cycles increases, the segmentation of transformation platform “disappears”. Subsequently, this phenomenon reappears. The transformation starting stress of charging specimens decreases more rapidly than that of the as-received. Hydrogen has a promoting effect on the generation of internal stresses in NiTi alloys. And the hindering effect of hydrogen on transformation and the promoting effect on internal stress are competing mechanisms.

The aim of this paper is to establish a mechanical-diffusion coupled constitutive model of NiTi shape memory alloys, which regards the above effects of hydrogen on mechanical behavior of NiTi alloys. In order to calculate the hydrogen concentration, stress and strain fields of NiTi alloy wires, and obtain the overall thermomechanical response of NiTi wire.

At the same time, in order to reduce the computational cost faced by the software when calculating the fully coupled analysis, the diffusion theory and scale conversion rule are introduced, combined with the developed constitutive model to describe the macroscopic thermomechanical response of NiTi alloy wires. The prediction results of the two methods are in good agreement with the experimental data.

Harmful Microstructures in Fatigue: Influence of Grain Morphologies and Orientations on Local Stress Distributions

Rémy Serre[1,*], Carole Nadot-Martin[2] and Philippe Bocher[3]

[1] École de Technologie Supérieure, 1100 rue Notre-Dame Ouest H3C 1K3 Canada, remy.serre@ensma.fr

Key Words: *Cellular Automaton, Micromechanics, High Cycle Fatigue, Grain Shape Effect*

Predicting where and especially when fatigue cracks will occur is a complex mater. In addition to the crystallographic orientation of the grain itself, the configuration of its neighborhood has a strong influence on the strain and stress levels generated during fatigue solicitations. As it is the worst configurations out of a large number of grains and neighborhoods that will drive the fatigue performance of a material, extreme value statistics have to be used. To do so, large set of data have to be generated in a reasonable CPU time.

Mean-Field Homogenization methods are fast, but they do not provide enough statistical information to be relevant. Although Full-field Finite Element simulations does provide a precise quantification of the neighborhood effect, the associated CPU times are very high and gathering sufficient data for extreme data statistics will require very high CPU times. There is a sort of compromise between these two approaches in the method based on Cellular Automaton (AC). Its CPU time is several orders of magnitude lower than Finite Element simulations and still provides precise localisation information. Thus, it is a relevant tool for gathering enough data to describe the statistical nature of the neighbourhood effects in polycrystals.

In the present paper, the AC method is applied to a microstructure with complex grain shapes. As an extension to Bretin et al. on close-to-equiaxal microstructure [1], the Eshelby Equivalent Inclusion Method (EIM) [2, 3] was developed for grains with various revolution ellipsoid shapes. The local stress field for different microstructures configurations were calculated. A large variety of aspect ratios and relative spatial orientations were documented for a 316L stainless steel, material known for its strong anisotropic elastic properties. The results were analysed to identify best as well as worst configurations for fatigue performance.

Key Words: *Trabecular Bone, Bone Adaptation, HR-pQCT*

Adaptation is the process by which bone responses to changes in loading environment and modulates its properties and organization to meet the mechanical demands. Trabecular bone, the spongy component of many bones, undergoes significant adaptation when subjected to external forces. It was found that intensive mechanical stimulation results in thicker and mechanically stronger bones and bone morphology with individual elements of this bone tissue, *trabeculae*, aligned along the loading direction [1]. In contrast, a lack of mechanostimulation induces a bone-mass reduction, thinning of trabeculae, and deterioration of mechanical properties [2]. Load-induced adaptation is implemented through resorption of old and fractured bone and formation of a new bone material. These processes are hypothesized to be driven by mechanical stimuli of bone-matrix deformation sensed by bone mechanosensory cells [3]. The exact nature of mechanical stimuli triggering bone resorption and formation activities in response to external loads is currently unknown.

This study aims to compare different mechanical stimuli on their ability to trigger load-induced adaptation in trabecular bone. To achieve this, developed 3D unit cells of trabecular lattice are developed with bone marrow in its intertrabecular space, reconstructed from two sets of high-resolution peripheral computed tomography (HR-pQCT) scans. The first set includes baseline scans of distal tibia of a human participant, the second one comprised scans of the same participant after a six-months-long high-impact exercise. The finite-element method is implemented for the baseline model loaded in compression, tension, and shear to calculate the magnitudes of several mechanical stimuli that are widely considered as candidates to trigger the bone adaptation. A user-material subroutine is developed to relate the magnitude of each candidate to changes in mechanical properties and shape of trabeculae in the baseline model. The obtained adaptation results are qualitatively compared against the follow-up model.

Microstructure-based modelling of thermomechanical behaviour of cast irons

Evangelia Nektaria Palkanoglou[1*], Minghua Cao[1], Konstantinos P. Baxevanakis[1], and Vadim V. Silberschmidt[1]

[1] Wolfson School of Mechanical, Electrical and Manufacturing Engineering, Loughborough University, LE11 3TU, UK

Key Words: *Microstructure, Thermal load, Cast iron, RVE, Micromechanics*

Thermomechanical behaviour of cast irons is computationally investigated in this work, employing a micromechanical approach. Cast irons form an integral part of industrial applications, since they are used extensively in numerous applications thanks to their good thermal and mechanical properties, excellent wear resistance, and competitive price [1]. Although cast irons were studied considerably, their thermomechanical behaviour and, especially, fracture at microscale is not yet fully understood. The main reason for this is their complex microstructure comprising graphite particles of different shapes, sizes, and orientations embedded in an iron matrix, which can be pearlitic, ferritic, or a combination of these two phases.

In order to identify the parameters that affect the fracture of cast irons under thermomechanical load, microstructures are characterised with scanning electron microscopy and the obtained scans are assessed with image processing tools. Using statistical analysis of the results, representative volume elements (RVEs) are generated with Python scripts. These comprise a ferritic/pearlitic matrix and graphite particles of various shapes (represented as ellipsoids) and are studied using a finite-element approach. An elastoplastic behaviour is assumed for both graphite inclusions and matrix, while a graphite-matrix interface region is modelled with cohesive finite elements [2, 3]. The focus of this study is on identification of fracture mechanisms at microscale and understanding the macroscopic performance of compacted graphite iron under purely thermal or thermomechanical loading. In addition, parametric analyses are performed to link different microstructural features to mechanical responses. The obtained results are expected to be useful in the future design and optimisation of this engineering alloy and similar metal matrix composites.

Microstructure-based Thermochemical Ablation Model of C/C Fiber Composites

Xiaobin Wang[1*], Peng Jiang[1], Weixu Zhang[1]

[1] State Key Laboratory for Strength and Vibration of Mechanical Structures, School of Aerospace Engineering, Xi'an Jiaotong University, Xi'an 710049, China,
Email: Wangxiaobin369@stu.xjtu.edu.cn

Key Words: *C/C composites; Thermochemical ablation model; Microstructure; Ablation recession rate*

The microstructure of carbon fiber-reinforced carbon matrix composites (C/C composites) have important effects on its ablation performance. However, the traditional macro-prediction methods underestimated the ablation recession rate and ignored the influence of microstructure [1, 2]. It is necessary to modify these methods to take the microscopic characteristics into account. Therefore, in this work, a thermochemical ablation model of C/C composites is proposed based on the evolution behavior of its microstructure. The ablation recession rate and surface temperature predicted by this model are in good agreement with the experimental results. Through the numerical analysis, we found that the ablation recession rate of the material without carbon fibers is much greater than that of the material containing carbon fibers. The ablation recession rate is influenced by the fiber orientation due to the change in thermal conductivity. The anti-ablation efficiency of the C/C composites can be improved by increasing its fiber radius, radiation coefficient, heat capacity, interphase density, and thermal conductivity coefficient. The thermochemical ablation model provides a guide for the design of better anti-ablation C/C composites.

Key Words: *carbon/UHWPE nanocomposites, equal channel angular extrusion, FEA*

Ultra-High Molecular Weight Polyethylene (UHMWPE) is widely used as a bearing surface in total and partial joint arthroplasty. In addition to medical applications, this polymer is utilized in the fields of ballistic protection, sports, and industrial tribology. The addition of carbon allotropes, such as nanographite or carbon black powders, to UHMWPE offers potential benefits including added conductivity, increased wear resistance, and introduction of micro-tracers for understanding microstructural behavior and monitoring damage [1]. The mechanical properties of these carbon/UHWPE nanocomposites can be enhanced by subjecting them to equal channel angular extrusion (ECAE) as a way to introduce large shear strains and achieve higher molecular entanglement of UHMWPE and better distribution of carbon nanoparticles [2, 3].

This paper presents numerical models developed to obtain an insight on the full-field distribution of shear strains during the ECAE process and to correlate the resulting microstructure with the overall mechanical and electrical properties of carbon/UHMWPE nanocomposites. Numerical simulations are conducted on macroscale (ECAE) and microscale (UHMWPE particles and carbon-polymer mixtures) utilizing finite element analysis and analytical micromechanical formulas. The composite material models are based on micro-computed tomography and microscopy studies. Numerical modeling results are correlated with the experimental observations of the extrusion forces and extruded billet shapes (ECAE models) and the overall material properties measurements obtained through thin-section tensile testing (microscale composite models).

Key Words: *Fiber Magnesium Laminates, Interlaminar Performance, Low-velocity Projectile Impact, Constitutive model*

Hybrid carbon fiber reinforced Epoxy (CFRE) composite core/magnesium alloy facesheet laminates are the latest generation of laminates [1]. They have been paid for more and more attention in the fields of electronics, vehicles, aerospace due to their high specific strength and modulus, good shock and energy absorption in comparison to other fiber metal laminates (FMLs). However, the application of the fiber/magnesium laminates is limited because of the weak bonding interface in them. In addition, information on the dynamic mechanical properties of fiber reinforced magnesium-based laminates is very limited [2].

In this work, we focused on the interlaminar performance and impact response of elnov fiber/magnesium alloy laminates (Mg-FMLs) with enhanced interface adhesion [3]. The interlaminar fracture behavior of the Mg-FMLs under different loadings was experimentally studied and the cohesive zone model (CZM) parameters for interfacial bonding layer of the hybrid laminate were extracted by inversion analysis based on the DCB experimental data. Moreover, dynamic response modelling of the FML specimens subjected to low-velocity projectile impact loading was carried out using the developed VUMAT subroutine implemented in ABAQUS/Explicit, and the predicted results were compared to the SHPB experimental results. Results show that the present Mg-FMLs exhibit higher interlaminar fracture toughness and impact resistance than those of traditional Mg-FMLs bonded with epoxy resin [4]. The predicted results for the low-velocity projectile impact are close to the experimental results, validating the correctness of constitutive and finite element models of the composite laminates under dynamic loading conditions. The overall fracture of the present Mg-FMLs under different loading conditions exhibits matrix and CFRP dominated mixed-mode failure because of high interlaminar properties. The research results provide an important reference for the design optimization and application of impact resistant lightweight fiber-metal laminated structures.

Key Words: *mudstone, cut slope, weathering, rigid-plastic finite element method, infinite slope, Bishop's method*

Weathering-induced deformation of cut slopes excavated in weak rocks is a significant concern for the long-term stability of the slope. In this study, a cut slope at the Tomei expressway was investigated by extensive geotechnical survey and laboratory tests over 50 years to reveal the weathering mechanism after the excavation. From the survey and test results, variation of the stiffness and strength due to weathering was grasped. Interpretation of the safety factor and change in the failure mode due to weathering was predicted by the rigid-plastic finite element method incorporating the strength degradation. A simple, analytical method combining the classical theories of slope stability is developed to predict the weathering-induced change in the safety factor and the failure mode.

Key Words: Validation, Generalized FEM, eXtended FEM, Hydraulic Fracture Propagation, Mixed-Mode, *p*-enrichments, Mesh Adaptivity

This work presents a 3-D Generalized/eXtended Finite Element Method (GFEM) simulation of hydraulic fracture process by coupling the solid/rock domain equations with the fluid flow within the fracture using the algorithm reported in [1]. The GFEM, which is based on *p*-hierarchical FEM enrichments, is combined with mesh adaptivity for the robust and computationally efficient simulation of mixed-mode brittle fracture propagation. Both *h*-refinement around the fracture front and *p*-enrichment in the analysis domain are used to control discretization errors. The fluid flow, descritized using a 2-D FEM, is modeled using the Reynold's lubrication theory and assuming a Newtonian fluid property. A Linear Elastic Fracture Mechanics (LEFM) model based on Irwin's criterion is adopted for the solid domain. The direction of fracture propagation is computed using Mode I, II, and III Stress Intensity Factors (SIFs) and Schöllmann's criterion [2]. SIFs are extracted using the Displacement Correlation Method presented in [3]. The formulation cabalities are demonstrated by its adoption to reproduce a set of two hydraulic fracture experimental tests with reasonable accuracy. This is followed by a series of parametric analyses on multiple interacting fractures to study the influence of treatment conditions (fluid viscosity, spacing and number of the fracture cluster and remote stress type) on their behavior.

A Machine Learning Assisted Multiphysics Model for Reliability Analysis of Underground Pipelines under Environmental Attack

Edel R. Martínez*, Solomon Tesfamariam

[1] The University of British Columbia, Okanagan campus, V1V 1V7, edel.rolando@gmail.com

Key Words: Multiphysics Problems, Random Fields, Hydrogen Environment Assisted Cracking

Past research in stress corrosion cracking (SCC) of pipelines widely relies on expensive and trial-and-error experimental methods to study material susceptibility to cracking under field operating conditions. This work developed a new methodology for using probabilistic multiphysics modeling and simulation of pipelines subjected to near-neutral pH SCC. The mechanism-based hydrogen damage model is solved from a sequence of two stages: colony evolution and cracking. That is, first we predict preliminary stages including time to initiation and starting crack dimensions. Then a second module is used to continue the calculation of the residual strength. Finite element models are validated by existing SCC experiments of X70 steel, with emphasis on the synergistic effects of mechanical and corrosion properties on the material degradation mechanisms. The solution pH and the potential variables are modeled as random fields. Other materials, environment, and stress random variables are considered, and particularly, the initial crack has an aspect ratio modeled from available field data. During uncertainty quantification of the finite element model, an assemble of metamodels is used to alleviate the computational burden of stochastic calculations. The assemble enables a very efficient Monte Carlo simulation, which is performed in the encapsulated algorithm. This surrogate assemble is validated and applied to sensitivity analysis and reliability analysis of the affected pipe. The proposed approach balances high-fidelity modeling with relevant random variables. Furthermore, the proposed approach can reproduce relevant mechanical and corrosion variables that affect stress corrosion crack growth rates. This fact could significantly reduce uncertainties associated with this type of SCC. The results revealed that the probability of failure due to burst is highly sensitive to the crack aspect ratio and toughness due to their influence on crack driving forces. The remaining life can be prolonged greatly by reducing the crack aspect ratio and increasing fracture toughness. In conclusion, it is expected that the presented approach can leads to improvement in the design for reliability of oil and gas pipelines.

Key Words: Phase-Field Fracture, Hydraulic Fracture, Multi-Resolution Methods

We present a multi-resolution scheme for simulating hydraulic fracture problems. We consider systems involving a coupling of fluid flow through porous media and within cracks with the mechanics of fracture. In particular, we develop a multi-resolution approach employing a coupling of global and local scales, with distinct treatments in each. Crack propagation is handled inside local subdomains instantiated on the fly in the vicinity of crack tips, using a phase-field method to facilitate the treatment of complex topological changes. The bulk physics are discretized over a global domain, where the fractures are assumed to be fixed and represented by embedded discontinuities. This separation imparts the approach with the benefits of the phase-field method in handling complex crack paths, without requiring the extraction of crack openings from a diffuse crack surface representation. To demonstrate the efficacy of our framework, we compare simulation results using this multi-resolution scheme to well-known benchmark problems in hydraulic fracture, including those with multiple, interacting cracks.

[4] Duke University, 27707, jdolbow@duke.edu

Key Words: Phase Field, Fracture, Crack Opening, Thermal Contact

Many phase-field formulations for fracture require fast and accurate computation or estimation of jump of quantities across the regularized cracks. For example, the traction-separation law in cohesive fracture, the crack-opening-displacement(COD)-dependent permeability in hydraulic fracture, and the COD-dependent thermal conductivity and the temperature-jump-dependent heat flux in thermal contact all require knowledge about the jump in certain quantities. To date, there have been many attempts at estimating the COD [1, 2, 3, 4, 5, 6]. In this work, we propose a PDE-based approach for estimating general jump quantities across cracks. In the same spirit of phase-field regularization, the jump is first regularized as a density function defined everywhere in the domain. The path-wise constant jump density field can then be obtained from a constrained minimization problem. With prior knowledge about the support of the phase field, a constant jump field over the entire support of the phase field can be recovered. The performance of the proposed method is studied using stationary prescribed cracks and a patch test for thermal contact. Finally, a regularized thermal contact formulation is developed and verified against sharp crack descriptions.

Key Words: *phase-field, fracture propagation, damage, composites, orthotropic materials*

Modern day composites have many potential applications in the production of structural components like fuselage, fairings, wing structures etc., as they possess high strength and stiffness-to-weight ratio. The structural components also require fewer fastening and machining parts. Despite the significant advantages of composites, several questions pertaining to the mechanical/failure behavior of composites remain unresolved. For instance, wing structures in aircrafts often withstand high lift and drag forces. Any composite material used in designing these components must withstand these forces without a significant risk of failure. The development of predictive numerical models is thus essential while understanding the failure behavior of composites. However, existing methods fail to accurately predict the various failure mechanisms, such as crack deflection, coalescence, and matrix cracking at the laminate interfaces. Here, we propose the use of an adaptive phase-field approach to address this class of problems.

We extend a recently developed adaptive phase-field method to model delamination in orthotropic laminated composites [1]. In the proposed approach, two sets of governing equations are simultaneously solved in a staggered manner. A second-order partial differential equation is solved to obtain a phase-field variable that predicts the damage evolution. A coupling between the mechanical equilibrium equations and the phase-field damage variable equation is achieved through a stress-degradation function. The dependence of the crack path on material orientation is incorporated by means of a penalized second order structural tensor in the crack surface density function [2]. Crack driving force was divided into individual fibre and matrix damage, corresponding to different failure modes across laminate [3]. An adaptive refinement strategy is finally suggested, to reduce the computational cost, that robustly discretizes the domain as the crack propagates. The computational mesh is partitioned into standard and refined regions, which is mapped onto a fixed background mesh with different approximation spaces. A continuous finite element approximation is used while partitioning the regions, weak continuity is then imposed at the interface using Nitsche's method. Benchmark numerical experiments were performed to demonstrate the efficacy of the approach to capture failure behavior in composite laminate by varying fibre orientation. Results exhibit the great capability of model to predict crack propagation which was either along the interface or it cuts the matrix. The numerical findings were validated by existing experimental and numerical studies.

Key Words: *phase-field, fracture propagation, layered media, subsurface fracture*

Fracture propagation in layered subsurface media is actively studied by engineers, and geoscientists. In various geo-engineered systems, such as, unconventional hydrocarbon reservoirs, enhanced geothermal systems, tunnels, and mines, fracture patterns in the subsurface play a critical role. Predictive numerical simulations are an essential tool to facilitate well-designed subsurface systems. However, despite significant advances in recent years, numerically predicting fracture propagation in the subsurface remains an outstanding challenge for the computational mechanics community. This is partly because the subsurface is highly heterogeneous and contains several layers with distinct mechanical properties, which dramatically affects the geometry of subsurface fractures. Depending on prevailing conditions of contrasts in elastic moduli, fracture toughness, interface inclination, and in-situ stress of surrounding layers, cracks may either arrest, penetrate, or branch at the material interface [1].

This study will extend a recently developed adaptive phase-field fracture model to layered materials [2]. In this approach, mesh refinement is required only in a small, diffused zone ahead of the crack tip while the rest of the domain is discretized using standard elements. The continuity between refined and standard elements is ensured by employing the Nitsche's method. The key advantages of the proposed methodology include an energetic approach to the crack propagation criteria, a natural crack-tracking framework through a phase-field variable, and reduced computational burden due to mesh adaptivity. Several parametric studies will be performed to study the effect of elastic stiffness contrast, toughness contrast, and interface inclination on fracture propagation in layered subsurface formations with perfectly bonded layer interfaces. Based on these studies, conclusions will be drawn on the conditions that result in fracture arrest, deflection, and penetration at layer interfaces in multi-layered formations.

Key Words: *Fracture phase-field model, One-cut Gaussian random field, Sintered silver nanoparticles*

Nowadays, sintered silver nanoparticles, a promising candidate for electronics interconnection materials, are widely adopted in emerging electronics technologies such as next-generation power electronics, polymeric devices, skin-mounted device, printable elastic conductors, and wearable printed circuits. Owing to its low sintering temperature, high melting point, and excellent thermal and electrical conductivities, sintered silver nanoparticles allow reliable electrical and mechanical interconnects to be used for various substrates and harsh environments. Essentially, sintered silver nanoparticles are typically heterogeneous with randomly distributed pores are ubiquitous.

Recent experimental investigations have revealed that porosity and also the pore-related geometries (size, number, shape, distribution and alignment) have significant impacts on the mechanical behaviour of random porous materials. However, existing studies focus on the porosity effect while ignoring other pore features such as pore size and pore shape. Our research is dedicated to a computational framework for generating isotropic/anisotropic random porous materials using Gaussian random fields with stochastic pore size and shape factor and addressing the mechanical properties and behaviour of brittle fractures using a fracture phase-field model with a preferred degradation function. Sintered silver nanoparticles with typical randomly distributed pores, as representative porous materials, are chosen for their promising applications in emerging fields such as power electronics and wearable devices. In order to emphasize the effect of pore size and shape, 420 random samples with a fixed porosity were generated to discuss the stress-strain response during fracture and to establish statistical relationships between pore feature distributions and mechanical properties such as Young's modulus, UTS, and average historical energy. Our findings suggest that the statical attributes of the pore sizes and shape factors significantly affect the material performance related to the mechanical properties and fracture behaviour, which could give a better understanding of the random porous materials and guide reliability-based material design and optimization.

Further studies can be done in the future to expand into the three-dimensional structure in order to gain a better understanding of the correlation of true microstructure with mechanical behavior. The relationship between three-dimensional spatial distribution features and mechanical properties can be investigated for random porous structures as well. On the other hand, a huge number of random samples generated by our approach can be studied more effectively by machine learning. Efficient and fast links between random porous structure and mechanical characteristics can be developed by machine learning, which can drastically reduce computational consumption and achieve microstructure-based material attributes more quickly.

Updated-Lagrangian XFEM Formulation for Ductile Fracture at Large Strain

Antonio Kaniadakis[1*], Jean-Philippe Créte[2] and Patrice Longère[1]

[1] Institut Clément Ader, Université de Toulouse, ISAE-SUPAERO, INSA-T, UT3/UPS, IMT Mines Albi, CNRS, 3 rue Caroline Aigle 31400 Toulouse, France, antonio.kaniadakis@isae-supaero.fr, patrice.longere@isae-supaero.fr

Key Words: *Ductile Fracture, Finite Strain, X-FEM, Updated-Lagrangian Formulation*

The numerical treatment of the whole process of ductile fracture remains a challenging task, particularly when FEM is employed. The well-known main issue regards pathological mesh dependence of the numerical results, not only in the softening regime induced by the more or less diffuse micro-defect growth, but also in the stages of strain localization and further crack propagation that are strongly controlled by the mesh size and orientation and not by physics. In the literature, non-local approaches are adopted to mitigate these effects but they require a calibrated length scale and mesh refinement, thus being time consuming. In order to get both mesh objectivity and low computation cost, we here propose to apply the XFEM to both weak and strong discontinuities, viz. strain localization and crack propagation. A three-dimensional methodology assuming small strain has been implemented into the commercial code Abaqus through a user-element (UEL), wherein the strain localization band is described through a cohesive plane embedded within the finite element (cohesive XFE), and the progressive loss of cohesion leads to crack formation (traction-free XFE), see [1]. We further extend this methodology considering large strain and rotation, relying upon the Updated Lagrangian formulation (U.L.) (see [2]), incrementally objective algorithms as proposed in [3], and various cohesive models. The main numerical issues, such as locking (see [4]) that were necessary to solve/overcome will be presented along with cases of increasing complexity (geometry, loading). A final assessment of the numerical approach implemented in Abaqus will be conducted by comparing numerical results to experimental results.

Key Words: X-FEM, coalescence, Smart Cut, SOI, SIF

It has been shown that the coalescence of pressurized penny-shape cracks leads to controlled fracture of silicon which is the basis of Smart-Cut process used to fabricate silicon on insulator (SOI) wafers [1]. In this study, we report the results of the simulation of multiple crack evolution and their coalescence using the eXtended Finite Elements Method (X-FEM). This approach can offer accurate and optimally convergent numerical solution of elastic fields using level sets functions and enrichment technique to define a crack [2]. We have addressed the problem with a 3D model and in linear elastic fracture mechanics framework. A multi-scale adaptive mesh has been developed in the form of 3D fractal mesh to optimize computation time. About 90% gain in computation time has been achieved compared to structured meshes. Neumann boundary conditions for pressure have been applied on crack interfaces. This type of load represents pressure in cavities produced by hydrogen gas created by H implantation followed by annealing during Smart-Cut process. Another contribution of this study is related to the determination of 3D stress intensity factors (SIF) with internal pressure applied on crack interfaces. Numerical results on SIF K_I have been compared to the analytical solution in the model case of isolated round penny-shape crack in equilibrium, demonstrating very good accuracy (less than 1%). The crack growth is taken into account in the model following Griffith's theory for brittle fracture [3]. The coalescence modeling has been possible by updating level sets and enrichments at the crack vicinity. The final challenge in this study is the modeling of experimentally observed cracks evolution [1] to explain physical aspects of cracks in the Smart-Cut process and to evaluate local instabilities related to crack size and shape.

A peridynamic fatigue model based on two-parameter remaining-life formulation

Dong-Jun Bang [1], Ayhan Ince[1*]

[1] Department of Mechanical, Industrial & Aerospace Engineering, Concordia University, Montreal, Quebec, Canada H3G 1M8, ayhan.ince@concordia.ca

Key Words: *peridynamic fatigue model, remaining-life, crack driving force, R-ratio effect*

The peridynamic fatigue model using the remaining-life concept was developed by Silling and Askari [1]. In this model, fatigue damage induced by cyclic loadings can be simulated by applying the remaining-life solution as a failure criterion. Herein, the remaining-life solution is based on only the single parameter of the core cyclic bond strain induced by cyclic loadings. Bang et al. [2] and Bang and Ince [3] showed that the model has a limitation of accounting for fatigue damage induced by both monotonic and cyclic loadings, i.e., effects of R-ratio are not considered in the peridynamic fatigue damage model.

To overcome this problem, a new peridynamic fatigue model based on two-parameter based remaining-life concept is proposed in order to take into account R-ratio effects in peridynamic crack growth simulations. Two-parameter remaining-life equation is formulated as a function of the core cyclic bond strain and maximum core bond strain considering two-parameter nature of fatigue damage process. The core cyclic bond strain and maximum core bond strain are regarded as two independent peridynamic crack driving forces in a new formulation of the PD fatigue damage model. The proposed model provides a capability that more accurate crack growth simulations can be obtained by accounting for two independent damage controlling parameters of the core cyclic bond strain and maximum core bond strain resulted from the cyclic and monotonic parts of a loading cycle, respectively.

The model results show the predicted crack growth rates computed by the model agree well with experimental data set of 2024-T3 and 7075-T6 aluminium alloys under four different R-ratio loading conditions of $R = 0$, $R = 0.33$, $R = 0.5$ and $R = 0.7$. The model predictions also show that two-parameter based crack growth driving force enables crack growth data sets at various loading conditions are collapsed on the predictive master curve of the model. The proposed peridynamic fatigue damage modeling approach provides efficient and accurate crack growth simulations by accounting for different R-ratio loading conditions. The unification of fatigue damage behavior under various cyclic loading conditions can be possible by accounting for two peridynamic damage controlling parameters of the core cyclic bond strain and maximum core bond strain in the formulation of the fatigue damage model on the basis of two-parameter based remaining-life formulation.

A unified nonlocal model for capturing discontinuous, multiphysical and multiscale behaviours of geomaterials

Haitao Yu [1*], Xizhuo Chen[1], Yuqi Sun[1], Xiaokun Hu[1]

[1] Department of Geotechnical Engineering, Tongji University, Shanghai 200092, China
*E-mail: yuhaitao@tongji.edu.cn

Key Words: *Peridynamic, Multiphysics, Multiscale, Discontinuous, Geomaterials*

A unified peridynamic model (UPD) is proposed to simulate the discontinuous, multiphysical and multiscale behaviours of geomaterials. The mechanical behaviours of the material points are reformulated by incorporating the bond tension-rotation-shear coupling effects, which makes the proposed model suitable for complex discontinuous problems in both three-dimensional spatial and two-dimensional plane conditions. The governing equations of bonds connecting material points are reformulated from the definition of bond deformation rates, leading to a rate-based expression of mechanical behaviour of solid particles. Three kinds of peridynamic parameters, corresponding to the compressive, shear and bending stiffness of the bond, are introduced to keep the consistence of the strain energy obtained from the proposed peridynamic model and from the continuum mechanics under arbitrary deformation fields. The damage evolution functions are introduced in the model to capture the loading-rate dependence of geomaterials. Moreover, a novel energy-based failure criterion, involving the maximum stretch, shear strain and rotation angle limits of the bond, is proposed to describe the nonlinear behaviors and progressive failure for geomaterials.

In order to further simulate the continuous and discontinuous mechanical behaviours of geomaterials under effects of different physical fields, a nonlocal multiphysics model is proposed in the framework of the UPD. A new force state vector is proposed by introducing the first Piola-Kirchhoff stress to enable the divergence of stress tensor at each material point to be expressed by averaging all the force state vectors in its support domain. It is also demonstrated that the new force state vector ensures the mathematical consistency between the strong form of peridynamic (PD) and the classical continuum mechanics (CCM) when the horizon of a material point approaches to zero. Then, a non-local Gauss's formulation is presented by transforming the displacement and traction boundaries in CCM into the non-local fictious boundary layers in PD, and this formulation unifies the variational framework of PD and CCM at both continuous and discrete levels. Furthermore, a fully implicit algorithm is developed to solve the general nonlinear problems such as fracture behaviours and large deformation of solid materials. Fianlly, a penalty method is employed to eliminate the zero-energy mode oscillation inherently observed in NOSB-PD, and the penalty force and penalty stiffness matrix are derived in the proposed implicit algorithm and numerical implementation.

To modelling the mechanical behaviours of the fluid transport in porous media, a unified non-local fluid transport model is developed along with the idea of UPD. First, a non-local governing equation of fluid transport is presented based on the UPD, and a novel flux vector state and a non-local Darcy's law is proposed to illustrate non-local fluid transport effects in heterogeneous saturated porous media. The proposed flux state vector ensures the non-local governing equation of fluid transport model in heterogeneous saturated porous media degenerates into the local one when the horizon of each material point approaches to zero. A non-local pressure gradient at each material point can be obtained by averaging all the flux state vectors in its horizon, which unifies the weak and strong discontinuities of pressure in heterogeneous saturated porous media in a consistent way. Second, a variational formulation of the unified non-local fluid transport model is developed. This variational formulation enables the proposed model to deal with complex boundary conditions, which is difficult or even impossible for current fluid transport models

based on Bond-based Peridynamics (BB-PD) and Ordinary State-based Peridynamics (OSB-PD). Third, a fully implicit algorithm combined with the Newton-Raphson method is introduced to solve the general non-linear problems in the heterogeneous saturated porous media.

For the simulation of multiscale behaviours of geomaterials, the PD model based on nonlocal theory is coupled with the finite element method (FEM) based on classical continuum mechanics, which can eliminate the boundary effects caused by nonlocal effects. The PD and FEM models are coupled by the hybrid region, which is based on the simplified energy equivalent method. In the hybrid region, there are three kinds of transition weight function: Heaviside function, linear function, and cubic function. The dynamic relaxation method is used to reach a solution. The computational accuracy of the coupling method with different transition weight functions is verified by comparing the results of numerical examples with the FEM results. The coupling method lays a foundation for multi-scale discontinuity problems.

The proposed model is verified by comparing its results with those from experimental observations. Numerical examples demonstrate that discontinuous, multiphysical and multiscale behaviours of geomaterials under dynamic loads are well captured by the proposed model.

Data-Driven Mechanics for Non-Local Solid Mechanics with Frankenstein's Method

Bram Lagerweij[1*], **Gilles Lubineau**[2]

[1] King Abdullah University of Science and Technology, Thuwal 23955 Saudi Arabia,
abraham.lagerweij@kaust.edu.sa
[2] King Abdullah University of Science and Technology, Thuwal 23955 Saudi Arabia,
gilles.lubineau@kaust.edu.sa

Key Words: Computational Solid Mechanics, Data-Driven Mechanics, Non-Local Models

A new data-driven method for solid mechanics is proposed. The fundamental idea is to use full field displacement measurements to obtain admissible solutions over larger domains, called patches. As these patches have been observed in real structures, they automatically meet most of the PDE characterizing the problem, especially internal equilibrium and constitutive equation. We then use a library of such patches to predict the response of new structures. To do so, patches are assembled as pieces of a jigsaw puzzle in a way that they meet the boundary conditions exactly while they meet some globally defined approximation of equilibrium and kinematic continuity. No assumption on the locality of the problem was made, as the objective of the method is to be model-free. For this purpose we use an overlapping domain decomposition method that is applicable to both local and non-local problems.

Frankenstein's method can be readily applied to non-local problem without much additional complexity compared to local formulation, as it is by essence formulated independently of the locality/non-locality assumptions. This should allow for a more natural implementation of plasticity, degradation and damage in the future, as these are commonly accompanied by localization issues [1]. One can also see this work as an extension of non-local methods. The accuracy of traditional non-local models such as peridynamics, phase-field or higher order gradient methods, depends upon the formulation of an accurate constitutive relation. But traditionally constitutive relations are found empirically, the choice of a material model is essentially arbitrary, one simply decides on a fit function which seems appropriate as long as some thermodynamic principles are satisfied [2]. Our work does not require such a heuristic approach, it is a first effort towards a uniform framework. Removing the heuristics comes with a price however, an increase of computation cost and measurement data hunger.

We will introduce the fundamentals of Frankenstein's Method illustrated by history independent examples in one and two dimensions. The main focus is the formulation of a weak form, which will allow for the approximation of the exact solution.

Dynamic Fracture in Glassy Polymers: Peridynamic Models

Florin Bobaru[1*] and Longzhen Wang[2]

[1] University of Nebraska-Lincoln, Lincoln, NE, USA 68588-0526, fbobaru2@unl.edu
(https://engineering.unl.edu/mme/florin-bobaru/)
[2] University of Nebraska-Lincoln, Lincoln, NE, USA 68588-0526

Key Words: *Peridynamics, Dynamic Fracture, Glass, PMMA, Interfaces, Fracture Process Zone*

Peridynamic (PD) models for dynamic brittle fracture have been shown to predict complex crack patterns, the crack speed, and interactions between stress waves and propagating cracks. The models have been validated against experimental results for dynamic crack growth in glass [1,2]. There is also a clear understanding why, in contrast, phase-field models have difficulties in matching some of the experimentally observed behaviour. Nevertheless, when the PD models for brittle fracture are applied to certain glassy polymers (e.g. PMMA), they lead to crack propagation speeds significantly higher than what is measured in experiments. We investigated the reasons behind these discrepancies and found that the likely culprit is softening due to heating near the crack tip: experimental evidence has been published showing significant heating/melting around the process zone in dynamic fracture in PMMA materials. We concluded that heat generated by high strain rates at the crack tip, or its softening effects, need to be taken into account if one aims of predicting dynamic fracture in PMMA.

We introduced a PD model ([3]) that implements a Heat Affected Zone (HAZ) around the crack tip in which a nonlinear (bilinear) elastic model is used before peridynamic bonds break, in order to affect the softening due to heat generation from high strain rates. The model with a softened region around the crack tip was able to reproduce the experimentally measured crack speed and the crack length evolution with high fidelity. The new peridynamic model allowed us to understand the relevant mechanisms in dynamic fracture of PMMA. With this model, we demonstrated the importance of the softened region around the crack tip in dynamic fracture of PMMA materials.

The model was then used to study the influence of strong and weak interfaces in bi-layered PMMA on crack behaviour [4]. Experiments have shown that PMMA layers exhibit dramatic changes in dynamic crack growth characteristics depending on the interface toughness and its location. We find that the presence of three factors/elements in the PD model are essential for being able to reproduce the observed fracture behaviour: (1) softening near the crack tip to account for changes in PMMA due to heat-generation induced by the high strain rates reached around the crack tip in dynamic fracture; (2) having independent extension (mode I) and shear (mode II) modes of fracture; and (3) using a two-parameter fracture model (that can match both the strength and the fracture toughness for any horizon size). Once these elements are in place, the PD model captures the experimentally observed dynamic fracture characteristics in bi-layer PMMA: cracks branching or not at the interface, depending on the interface location; crack running along the interface and punching through the second PMMA layer; slight crack path oscillations near the far end of the sample. The computed crack speed profiles are also close to those measured experimentally. The model reproduces the slight crack acceleration seen before the crack tip reaches the interface, and the sudden drop in crack speed once passed the interface.

We conclude that dynamic brittle fracture models for PMMA require extra components compared to those that work for dynamic fracture in glass, for example. Moreover, the presence of interfaces constitutes an important benchmark against which computational models for dynamic

fracture need to be tested against: a model can perform well when simulating dynamic brittle fracture in a homogeneous sample, but fail when the sample is simply a layered construct of the same material.

Employing a Bézier curve model for simulating microstructure generation during the additive manufacturing process to inform microstructure aware material models

Jeremy Trageser[1]*, John Mitchell[2] and Theron Rodgers[3]

[1] Sandia National Laboratories, jtrages@sandia.gov
[2] Sandia National Laboratories, jamitch@sandia.gov
[3] Sandia National Laboratories, trodger@sandia.gov

Key Words: additive manufacturing, peridynamics, microstructure aware model

The microstructures of additively manufactured materials are spatially heterogeneous and highly process dependent. Moreover, engineering properties such as strength and toughness are sensitive to microstructure morphologies resulting from the manufacturing process. The creation of microstructure aware material models, in fields such as peridynamics [1], requires data describing the underlying microstructure.

This presentation will discuss recent work on a model employing the Metropolis Monte Carlo method for simulating additively manufactured microstructures. The proposed model allows flexibility in the process parameters which facilitates the analysis of the impact of process parameters on the generated microstructure. This model is implemented into the open source code SPPARKS [2].

Fracture analysis of bimaterial interface with the residual thermal deformation by peridynamic model

Heng Zhang[1] **and Xiong Zhang**[2*]

[1] Tsinghua University, Beijing China 100084, hengzh@163.com
[2] Tsinghua University, Beijing China 100084, xzhang@tsinghua.edu.cn

Key Words: *Peridynamics, Bimaterial fracture, Residual thermal deformation, Interface delamination*

In this work, the role of residual thermal deformation on bimaterial interface fracture is investigated by the peridynamic model. First, the formation of peridynamic bond force state considering thermal effect is given for the bimaterial elastic behaviours modeling. The energy release rate of bimaterial interface crack with the thermal deformation is computed with the modified peridynamics-based virtual crack closure technique (PD_VCCT) model. An extended peridynamic mixed-mode bond failure model considering thermal effect is proposed for interface bond failure analysis, and a node to node peridynamic contact model is introduced for the frictional contact modeling of interface cracks. Then, some examples are investigated for the model verification and application. The deformation and fracture behaviours of bimaterial specimens are predicted with the proposed peridynamic models, and the role of residual thermal deformation is studied.

Quasistatic Fracture using Nonliner-Nonlocal Elastostatics with an Analytic Tangent Stiffness Matrix for arbitrary Poisson ratios

Patrick Diehl[1*], and Robert Lipton[2]

[1] Center of Computation & Technology, Louisiana State University
[2] Department of mathematics, Louisiana State University
[3] Affiliation, Postal Address, E-mail address

Key Words: Quasistatic fracture, nonlinear-nonlocal elastostatics, hard and soft loading

We use nonlinear-nonlocal field theory for numerical simulations of quasistatic fracture. The model used is a regularized nonlinear pair-wise (RNP) potential within the peridynamic formulation. In addition, to the tensile force, a hydro force is added to allow arbitrary Poisson ratio. The potential functions are analytic and smooth. This fact allows us to write the entries of the tangent stiffness matrix analytically thereby saving computational costs during the assembly of the tangent stiffness matrix. We validate our approach against some state-based peridynamic model using numerical differentiation for the tangent stiffness matrix and classical continuum mechanics. In addition, we show stable crack growth for hard loading. Our approach is novel in that only bond softening is used, as opposed to bond breaking.

Study on thermal fatigue of nickel-based superalloy composites using Peridynamics method

Key Words: *Superalloy Composites, Peri-Dynamics, Thermal Fatigue, Damage,*

Nickel-based superalloy is a metal composite material with nickel as matrix and reinforcement. It has high strength and resistance to oxidation and corrosion at high temperatures, and has a wide range of applications in the fields of transportation, aerospace and energy. Experimental research on fatigue-resistance performance of nickel-based superalloys in high-temperature extreme environments has disadvantages such as complex experimental procedures, high research costs, and low efficiency. Herein, a temperature-dependent fatigue crack growth model of conventional peri-dynamics（PD）was established to simulate the fatigue crack growth behavior of graphene/nickel-based superalloy composites under thermal cyclic loadings. The effects of thermal cycle amplitude and graphene content on the thermal fatigue crack growth behavior of the superalloy composites are studied. The PD method describes the damage behavior of composite materials by solving the spatial integral equation, which effectively avoids the singular solution of the damage simulation crack, and the simulation calculation accuracy of the thermal fatigue crack growth behavior of the material is high. The present PD model provides a new idea for the numerical study of mechanical behavior of metal composites under extreme environment.

Key Words: Crystal Plasticity, Dislocation Sources, Stochastics, Ferrite

Micro-scale mechanical tests, such as micropillar compression tests or microtensile tests, play an important role in understanding the mechanical behavior of metals. Complementing these experiments by simulations can give additional insights into the observed behavior and allows for predicting the behavior in polycrystals. However, traditional crystal plasticity models fail to capture the heterogeneous deformation within a single crystal and the variations in the stress-strain curves between similar samples that are observed in experiments. These stochastic variations arise because of the limited number of dislocation sources present in the samples. On the other hand, simulation frameworks which do account for the stochastics of dislocation sources, such as discrete dislocation dynamics, come with significant computational cost and complexity and are often restricted to small displacements. This impedes the application of these simulation frameworks to full microscale experiments.

We present a numerical framework [1] which models the plastic deformation resulting from slip on crystallographic slip systems, similar to the approach taken in crystal plasticity, but which does account for variations in critically resolved shear stresses between atomic planes. These variations are linked to the physics and stochastics of dislocation sources. By using some verified assumptions, only small adaptions to a standard crystal plasticity code are needed in order to implement the model. This allows for simulations up to large strains, in a finite deformation setting. The numerical framework is used to study the behavior of microtensile tests of ferrite monocrystals, performed by Du et al. [2]. It is shown that the discrete slip plane model, contrary to a traditional crystal plasticity model, is able to predict the diversity of active slip systems, the heterogeneous deformation and the variations in the stress-strain curves that are observed in the experiments. Furthermore, the model is applied to samples consisting of multiple grains. Here, the competition between stochastic effects and microstructural features is studied.

Key Words: *Phase Field, Microstructured Media, Rate Effect*

Continuum damage models that possess an internal length scale address the mesh sensitivity of earlier damage models wherein the response becomes more brittle as the mesh is refined. However, in many applications the crack-tip damaging zones for propagating cracks tend to be overly diffuse and broad. While the phase field formulation derives from a different energy statement, the final form of differential equation resembles a gradient damage model, albeit with some differences in the source term and stress reduction function. These differences improve the phase field model response by reducing diffusion in damaged regions.

We consider the elastodynamics problem coupled with a hyperbolic phase field model. The rationale for using a hyperbolic phase field model is the finite speed of propagation of waves and damage in solid materials. This argument motivates the phase field model in [1] and the continuum damage models in [2, 3]. We present elliptic, parabolic, and damped hyperbolic forms of phase field differential equations and describe the interaction between the phase-field time scales (where present) and the time scale of dynamic loading in a 1D problem. The rate effects of the phase field models will also be compared with a continuum damage model. Understanding the induced material rate effects based on intrinsic parameters of the phase field model is important for extending the model to more complex 2D and 3D problems. Next, the asynchronous spacetime discontinuous Galerkin (aSDG) method [4] is used for 2D solutions. Specifically, the failure response of microstructured media composed of repeating unit cells is sought. The metamaterial microstructure is designed to delay the transfer of energy and to decay stress amplitude as waves pass through a slab of material. Finally, we briefly discuss applications of this accurate but computationally expensive continuum model for fine-tuning the parameters of extreme reduced order models (ROMs) based on discrete representations of grids of metamaterial cells.

Key Words: *Brittle fracture, Energy limiter, Crack band theory, Energy decomposition, FEM*

We present a new scalar damage model for brittle fracture under quasi-static and dynamic loading conditions in both 2D and 3D problems. In contrast to existing damage theories, the new development is derived in the context of scalar damage theory, but the damage variable is defined by means of the energy limiter theory [1] with an introduction of the damage threshold. The model is further enhanced with crack band theory [2] and energy decomposition [3]. Finite element discretization for the developed approach at small strain for localized brittle fracture is given. The developed damage model consists of three major ingredients: (i) the energy limiter theory is introduced as the foundation of the developed formulation; (ii) the crack band theory is to regularize the formulation to avoid mesh-dependent solutions; (iii) the split energy density uses to differentiate fracture behavior between tension and compression modes, preventing the non-physical crack in compression domains. We present several representative numerical examples to show the performance and accuracy of the developed damage model.

This study present a consistent description of the cohesive traction-separation law for seamless transition from weak- into strong-discontinuities. The fracture process can be divided into two stages to differentiate discontinuities in the displacement field around a crack tip. At the first stage of the fracture process, the displacement field changes from continuous to weakly-discontinuous ones due to the pseudo-jump discontinuity of the strain field caused by the stiffness reduction followed by material softening. The stiffness reduction is represented by the cohesive traction-separation law that is incorporated into a material constitutive law by the introduction of apparent strain caused by the crack opening displacement and the local balance equation between cohesive traction and principal stress. Moreover, we employ the micromorphic approach [2] that allows us to connect between microscopic variables representing apparent strain at local material points and micromorphic variables corresponding to that at global domain. As a result, the transition of the displacement field from continuous to weakly-discontinuous ones is realized by diffusive approximation. At the second stage, the displacement field is developed into jump discontinuity, as it is called the strong discontinuity by an explicit crack opening along with the material softening behavior. To realize a discrete crack opening, a finite cover method (FCM) [3] is employed by the combined use of the cohesive traction-separation law. The same cohesive traction-separation law is applied to keep consistent description between these two stages of the fracture process. The capability of the proposed method is demonstrated through several numerical examples.

Key Words: Damage mechanics, gradient regularization, non-local model

While damage mechanical models have been developed for decades now, the transition from diffuse degradation to a single fracture zone still remains a difficulty. Indeed, beyond a certain loading level, damage models generally lead to localized solutions of the associated continuum mechanics problem. The localized area corresponds to a crack but, without regularization, the problem becomes ill-posed, which results into spurious mesh dependency, e.g., the dissipated energy tends to zero as the finite element size tends to zero. Various solutions have been proposed in the literature [1], relying on a spatial non-local treatment of the regularization. The driving forces are averaged to introduce an internal length that enforces mesh independency. The averaging can be conducted directly or through an auxiliary boundary value problem. The internal length may be constant, in which case all interactions are not cut by a fully damaged zone, or the internal length can evolve with stress to account for boundary conditions and cut the interactions across a crack.

The aim of this paper is to present a non-local gradient regularization technique called the Eikonal non-local gradient model [2]. It is a gradient regularization which replaces the classical internal length by a varying metric originating from the acoustic wave speed. The potentially anisotropic metric evolves with damage, as in phase-field models, thus cutting interactions when the damage reaches one. The first part of the contribution presents this model and the associated properties on a 1D problem in tension. A comparison to other classical methods is also given. This example shows the good behavior of this regularization technique. It is shown that the evolving characteristic length leads to a rather sharp and brittle post-peak behavior. A plasticity model is then coupled to damage in order to decrease the brittleness of the mechanical response. This choice is illustrated to better understand the interactions between damage, regularization and plasticity.

Entropy-based damage model for fatigue behaviour of lead-free solder materials

Ying Guo[1], Xiaoyue Ding[1], Long Chen[1] and Xu Long[1*]

[1] School of Mechanics, Civil Engineering and Architecture, Northwestern Polytechnical University, Xi'an 710072, People's Republic of China

Key Words: *Entropy-Generation; Damage Model; Fatigue Behaviour.*

Solder materials are playing an increasingly important role in the electronic packaging structures in the development of electronic products. The mechanical reliability of packaging structures is directly related to the service life of the entire device or system, especially under harsh application conditions. In view of the fact that the CTE varies greatly for different materials in the package structure, the deformation of the packaging structure due to temperature change during thermal cycling will lead to mismatched thermoelastic deformation and stress concentration between different materials. Thereafter, selecting and describing the mechanical properties of solder materials has become crucial from the practical viewpoint.

In order to describe the influence of damage accumulation on the structural properties of the packaging material under the effect of cyclic loaded thermal mismatch, low cycle fatigue experiments were performed in the present study on Sn-3.0Ag-0.5Cu (SAC305) specimens at a strain level of 0.12 subjected to different temperatures and different strain rates. Based on the Newtonian mechanics and the thermodynamic theory, the entropy generation was derived as a damage parameter. Combined with the strength degradation under different cyclic loading conditions, the other parameters are determined to be related with the damage parameter. The relationship between the number of cycles and the peak stress for 400 loading cycles at various temperatures and a strain amplitude of 0.01. Apparently, the applied 400 strain cycles in this study are sufficient to result in the evolution and also the stabilization of peak stress for SAC lead-free solder materials. After comparing the peak stress at different temperatures, it can be found that SAC305 exhibits obvious temperature softening phenomenon, as its peak stress decreases as the number of cycles increases. Eventually, the damage evolution is proposed by correlating with temperature and strain rate, which to our knowledge has never been realized before for lead-free solder materials. By expressing the entropy generation as a function of variables such as stress tensor, plastic strain and temperature, the proposed damage factor comprehensively covers the influence of plastic work, thermal loading and other loading factors. In accordance with the quantitative law that fatigue entropy increases with the number of cyclic loading during fatigue deformation, the damage evolution law during temperature cycling is determined, thus establishing a damage-entropy generation model for packaging materials, which can reasonably describe the evolution law of accumulated damage of solder joints. In order to further elucidate the microscopic evolution of SAC305 under different cyclic conditions, the microstructure of SAC305 after fatigue tests was also examined by a scanning electron microscope (SEM).

Fracture of A neo-Hookean Sheet: An Arc-Length Method-Based Phase Field Model and Crack Tip Fields

Yin Liu[1*] and **Brian Moran**[1]

[1]King Abdullah University of Science and Technology, Kingdom of Saudi Arabia
E-mail address: yin.liu@kaust.edu.sa; brian.moran@kaust.edu.sa

Abstract: In this talk, we present damage effects on the crack tip fields in a neo-Hookean sheet based on a phase field model. We first introduce 1D and 2D phase field models which are able to track non-monotonic evolution of the equilibrium paths in facture process. In the incremental governing equations, a supplementary arc-length equation is introduced and consistent stiffness matrices are implemented [1]. The snap-back phenomena in fracture of a 1D bar and a 2D notched long strip are captured. We calibrate the material parameters using an energy based approach. We observe good agreement between the simulation and the experiment for the 2D notched strip in different loading cases [2] using only a single set of calibrated parameters. Based on the results of the phase field models, we derive asymptotic crack tip fields of a neo-Hookean sheet with prescribed distribution of the material damage. The features for the crack tip fields with the effect of material damage are summarized. We observe that the crack tip fields at the crack front are similar when the crack advances. The stress field shows a peak value in the front of crack and decreases to zero as the distance to the new crack tip goes to zero, rather than shows the singular behavior observed in results based on pure hyperelasticity [3,4]. Also, due to the presence of material damage, the stress near the crack faces is significantly reduced. These results provide new insights in understanding fracture mechanism for hyperelastic materials in the area of soft robotics and biological tissue.

Highly Anisotropic Plasticity of Lath Martensite – Computational Modelling and Comparison with Experiments

Vahid Rezazadeh[1], Roy Kerkhof[1], Tijmen Vermeij[1], Francesco Maresca[2], Marc Geers[1], Johan Hoefnagels[1], Ron Peerlings[1*]

[1] Eindhoven University of Technology, PO Box 513, 5600 MB Eindhoven, Netherlands
r.h.j.peerlings@tue.nl
[2] University of Groningen, Nijenborgh 4, 9747 AG Groningen, Netherlands

Key Words: computational micromechanics, crystal plasticity, experimental characterisation, advanced high strength steel

Advanced high strength steel grades based on dual phase or complex phase microstructures employ carefully designed mixtures of hard and soft phases to achieve a strong and ductile effective material response. Among these phases, lath martensite is the hardest and its role is thus to provide strength to the system. At the same time, it is quite brittle, hence limiting the overall ductility of the material. However, there is an increasing amount of experimental evidence of large plastic strains occurring in lath martensite [1]. They tend to occur in grains which are oriented such that the inter-lath boundaries experience a high shear stress. It has therefore been hypothesised that the plastic deformation occurs in thin (nm scale) retained austenite films, trapped between the laths, which by virtue of the orientation relationships always have slip systems parallel to the lath boundaries [2]. Developing a deeper understanding of this phenomenon is of practical relevance because it may provide a pathway to improve the ductility of the material at no (or limited) cost in terms of loss of strength.

Our objective in this study is to formulate an aggregated model for lath martensite plasticity, based on the hypothesis of pronounced slip in interlath retained austenite films, and compare predictions made by microstructural simulations based on the model with microscale experimental observations on a dual phase steel grade. The modelling targets the level of individual packets. It is founded on a full, conventional BCC crystal plasticity representation of the laths within the packet. The additional plastic deformation model facilitated by the austenite films is accounted for by adding (only) the three FCC slip systems parallel to the habit plane (and thus to the interlath boundaries) to the crystal plasticity description. Combining the resulting model with conventional crystal plasticity for ferrite allows us to capture the plastic activity distribution observed experimentally in dual phase microstructures.

Key Words: Ductility, Crystal Plasticity, Continuum Damage Mechanics, Fast Fourier Transform

Ductility is an important property that describes the amount of macroscopic deformation a material can endure before failure. Ductility can vary significantly based on geometric or microstructural size effects, especially at sub-millimeter length scales. Many previously developed finite element (FE)-based crystal plasticity models incorporate porous plasticity or continuum damage mechanics (CDM) to predict ductile failure. However, such FE models require significant computational resources. Fast Fourier transform (FFT)-based models are a growing alternative to FE-based models as they can accurately predict micromechanical fields at a fraction of the cost of traditional FE models. Several previously developed FFT-based models have incorporated either crystal plasticity or CDM; however, there remains a need to couple both methods together to predict ductile failure in polycrystalline materials. Using an FFT-based crystal plasticity method, we explore the effects of specimen geometry and microstructure on macroscopic ductility. This work incorporates a nonlocal triaxiality-based CDM formulation into a large-strain elasto-viscoplastic fast Fourier transform (LS-EVPFFT) model [1] to predict ductile failure in polycrystalline microtensile copper coupons. Simulations with the damage-enabled LS-EVPFFT model are compared to the macroscopic and micromechanical response from copper microtensile specimens characterized with electron backscatter diffraction (EBSD) and in situ digital image correlation (DIC). The low computational cost of the damage-enabled LS-EVPFFT model allows for the macroscopic ductility and ductile failure location of polycrystalline materials to be tractably predicted. This work is part of a continuing effort to develop models that accurately represent the entire elastic-plastic-failure loading process of complex 3D polycrystalline materials while retaining low computational cost.

Lipschitz Regularization For Softening Material

Nicolas Chevaugeon[1], **Nicolas Moës**[1,2]

[1] Centrale Nantes, GeM, UMR 6183, 44321 Nantes, France.
[2]Institut Universitaire de France (IUF), 75005 Paris, France.
nicolas.chevaugeon@ec-nantes.fr, nicolas.moes@ec-nantes.fr

Key Words: Softening, Localization, Regularization, Lip-field

The Lip-field approach is a new regularization method for softening material models. It was presented first in [1] providing one-dimensional simulations for damage and plasticity and was recently extended and implemented for two-dimensional problems [1]. In the Lip-field approach, the mechanical problem is formulated as the minimization of an incremental potential, function of the displacement field and internal variables. The potential itself is not regularized and has essentially the same form as in a local formulation. It does not contain any term depending on the spacial variations of the internal variables (like the Lapalacien) as is the case in typical phase-field approach [3, 4]. In the Lip-field approach, the regularization comes from the addition of a **Lipschitz** constraint on the damage field. In other words, the difference between the damage values at any two points must be less than the distance them, divided by a characteristic length. A discrete version of the Lipschitz constraint in the context of the finite element-method is constructed, defining a convex discrete subspace. Then a resolution scheme is presented, based on an iterative staggered scheme. The displacement field is sought for a given damage field by minimizing the potential with regards to the displacement, leading to classical equilibrium equations. Then at fixed displacement, the damage field is the minimizer of the potential, under the discrete Lipschitz constraint, the latter leading to a convex minimization, with convex constraint, solvable with standard interior point cone programming. In order to drastically reduce the complexity, we detail the construction of bounds of the subdomain where the constraint need to be explicitly unforced. The contribution is concluded by two-dimensional examples demonstrating the capability of the approach.

Key Words: *Solid-like shell, XFEM, Failure, Thin-walled structures, Necking, Traction separation law*

Marine structures subjected to different extreme conditions may undergo large inelastic deformation, leading to the formation of highly localized zones of intense straining and, ultimately to the onset of fracture and failure. The experiments performed on thin metal sheets under different loading conditions have shown a competition between necking and cracking phenomena [1]. Furthermore, Woelke et al. [2] showed that the traction separation law that governs the failure process zone after crack initiation, evolves as a function of crack extension because the law is affected by the evolution of necking ahead of the crack tip. Therefore, the relationship between stress state, boundary conditions, and necking need to be thoroughly investigated in order to incorporate necking and cracking initiation and evolution into a physically based objective failure model. This contribution focuses on a continuum modeling approach combined with a discrete modeling approach (XFEM) to simulate the interaction of necking and cracking phenomena. XFEM is incorporated into a geometrically nonlinear discontinuous solid-like shell element [3] to simulate failure in thin-walled structures. Special attention will be given to obtain an objective traction separation law for the cohesive zone modelling, and failure initiation and orientation criteria. The criteria for the requested mesh density come from the curvature of crack and a proper representation of stress and strain field in a cracked region. The required mesh size that can properly capture local effects for accurate calculation of crack initiation after necking and subsequent crack propagation will be demonstrated in this contribution.

[2] Institute of Mechanics and Computational Mechanics, Leibniz Universität Hannover, Appelstraße 9a, 30167 Hannover, Germany, nackenhorst@ibnm.uni-hannover.de

Key Words: anisotropic damage, concrete, constitutive modelling, ABAQUS, thermodynamics, elastic–brittle material, damage mechanics, tension

The development of an elastic brittle anisotropic damage constitutive model for plain concrete at the mesoscale under tensile loading is presented. At this scale concrete is considered as a three-phase heterogenous material consisting of aggregates, cement mortar and interfacial transition zone (ITZ). In this work the aggregates are considered as elastic undamageable inclusions, while a thermodynamically consistent tensorial damage model is used for the cement mortar in conjunction with a traction separation law for the ITZ. Within the framework of continuum damage mechanics (CDM), the theory of internal variables, the thermodynamics of the irreversible processes, the effective stress and energy equivalence hypotheses are used such that the three-dimensional constitutive equation of the elastic brittle damageable cement mortar is written in the effective (undamaged) configuration.

Within a thermodynamic framework, the damage initiation and evolution mechanism in the elastic range due to Mode I, II and III micro-crack propagation in the ITZ and in the cement mortar under tension is investigated. The different contributions of the second-order damage tensor components to the mesoscopic anisotropic reduction in stiffness of concrete are also demonstrated.

The damage model is implemented into the advanced FEA program (ABAQUS/standard) through a user-defined material subroutine (UMAT). This work shows that the mesoscopic damage is initiated and begins to evolve and the micro-mechanical properties of concrete start to degrade earlier than that observed at the macro level. The performance of the presented phenomenological framework is verified by comparing the numerical predictions with the experimental tests of concrete under monotonic uni-axial tension.

Abstract:

Since the drastic decrease in the lifetime of heat-resistant alloys under creep and creep-fatigue loads at elevated temperatures was attributed to the acceleration of intergranular cracking [1], the degradation of the crystallinity around a grain boundary, which causes brittle intergranular cracking under creep loading at elevated temperatures, was analysed by using a molecular dynamics analysis of a bicrystal structure. The local crystallinity was found to be degraded by the accumulation of dislocations and vacancies around the cracked grain boundaries [2]. In this study, the GEAM (Generalized Embedded Atom Method) interatomic potential was optimized for the analyses at elevated temperatures. The potential parameters were optimized to reproduce lattice constant, cohesive energy, elastic constants and melting temperature within the error of 5%. The determined potential explained these physical parameters well. The deformation and fracture behaviour of bicrystal structures were analyzed at 973 K, which is the representative operating temperature of the advanced thermal power plants.

It was found that the stress relaxation appeared even under the application of uniaxial stress of which magnitude was 50% of the yielding stress of the bicrystal structure. This stress relaxation was caused not by growth of dislocations but by the activation of atomic diffusion around the grain boundary. Outdiffusion of component atoms from the grain boundary region was accelerated at elevated temperature. Slight grooving also started to appear in the grain boundary region. The outdiffusion was drastically accelerated when the lattice mismatch between the nearby grains became large. The lattice-mismatch-induced local strain distribution caused the acceleration of atomic diffusion around the grain boundary. The drastic decrease in the density of atoms around the grain boundary degraded the effective strength of the grain boundary, and thus, intergranular cracking was accelerated by the degradation of the crystallinity around the grain boundary. These analytical results agreed well with the experimental results of the accumulation of vacancies and the degradation of the strength of grain boundaries with large lattice mismatch. The local concentration of free energy around the grain boundary was found to be a driving force of the outdiffusion. The local concentration of free energy was attributed to the strain energy caused by the lattice mismatch and mismatch of elastic constant between the jointed grains in the bicrystal structure. The concentration field was explained by using the modified Arrhenius equation where the effective activation energy changed as a strong function of mechanical stress.

Key Words: *Spot welding, High-Strength steel, HAZ, Crack Growth, Finite Element Analysis*

It is common to use spot welding when assembling high-strength steel plates for automobiles. Because of the effect of Heat Affected Zone (HAZ) generation where spot welding is applied, there is a problem in the accuracy of predicting the fracture of the spot-welded material [1][2], and the deformation behaviour of the vehicle body cannot be accurately reproduced. In addition, since there are many welding combinations such as steel grades and the difference in plate width and plate thickness, a general evaluation method is difficult to be established. Therefore, the aim of this paper is to develop a crack initiation and propagation prediction method for spot welded steel plates that can be applied to various combinations of steel grades and thicknesses.

Tensile tests were conducted on spot-welded high-strength steel sheets of 590 MPa, 980 MPa and 1180 MPa grades. The fracture strength and fracture strain were obtained and crack initiation and propagation behaviour were observed. In addition, fracture surfaces were observed with a scanning electron microscope, and the location of crack initiation and crack propagation mechanisms were analysed.

Also, micro-tensile tests were performed using micro test pieces collected from the spot-welded steel sheets to clarify mechanical properties around welding zone. Meanwhile, Vickers-hardness around HAZ was measured by nanoindentation tests. Based on above experimental results, we introduced shift factors of stress-strain curve around the spot welded zones and finite element model of spot-welded steel sheets were developed. Then, numerical simulations were carried out and compared with experimental results.

The results show that the fracture strength and fracture strain of spot-welded high-strength steel sheets were quantitatively predicted, and crack initiation and propagation behaviours were also reproduced successfully.

As a type of phase transition in natural rubbers, strain-induced crystallization is a phenomenon where amorphous polymer molecules transform to crystallites under the course of extension. Strain-induced crystallites are assumed to play an important role in the self-reinforcement and the crack growth resistance of natural rubbers. In this contribution, strain-induced crystallization of natural rubbers under various loading scenarios is investigated numerically. To this end, a finite element computational framework is constructed on the basis of a recently developed theory for strain-induced crystallization [2]. Its prediction is validated with infrared thermography-based quantitative surface calorimetry measurements under equibiaxial loading condition [1]. Finally, generalization of the computational model in biaxial tension with different biaxiality ratios will be used to analyze the self-reinforcement mechanism in natural rubbers.

Key Words: *Stochastic Collocation Method, GTN Model, Cohesive Zone Model, Ductile-To-Brittle Transition Region*

The contribution of this study is to discuss a dispersion of a fracture toughness predicted by the enhanced Gurson-Tvergaard-Needleman model (GTN model) [1, 2, 3, 4] within the ductile-to-brittle transition region. The enhanced GTN model, which has been devised to incorporate a cohesive zone model into a GTN model, is employed to realize the complex fracture behavior owing to the transition from a ductile fracture into a brittle fracture according to the temperature change in metallic materials. The GTN model represents the shrink of the yield surface with increase in void volume fraction due to void nucleation, growth, and coalescence. On the other hand, the cohesive zone model realizes the process of stress release along with the brittle crack propagation after the maximum principal stress reaches local tensile strength. The variation of dispersion of the fracture toughness due to temperatue change is predicted by assessing the uncertainties of both the void nucleation and the local tensile strength in our finite element simulations equipped with the enhanced GTN model. The obtained numerical results are statistically evaluated by stochastic collocation method [5]. In addition, we represent the change of the dispersion of the fracture toughness by introducing dependence of the initial yield stress, hardening behavior and local tensile strength on temperature in the enhanced GTN model. To demonstrate capability of our developed numerical analysis, the cumulative density function of the fracture toughness is compared with that obtained by the experiments at the low-, room- and ductile-to-brittle transition temperatures.

A coupled immersed boundary-material point method for shock-structure interaction and dynamic fracture

Ruichen Ni[1] and Xiong Zhang[2*]

[1] Tsinghua University, Beijing 100084, PR China, nrc18@mails.tsinghua.edu.cn
[2] Tsinghua University, Beijing 100084, PR China, xzhang@mail.tsinghua.edu.cn

Key Words: *shock-structure interaction, dynamic fracture, immersed boundary method, material point method, Riemann solver*

Shock-structure interaction is a class of extreme fluid-structure interaction (FSI) problems and always leads to dynamic fracture and fragmentation of solid structures in engineering applications. For its importance in safety and security, this problem has attracted extensive attention in recent decades. And, the development of efficient and powerful algorithms to simulate these phenomena is an active field of research.

Since being first introduced by Peskin[1] in 1970s, the immersed boundary method (IBM) has shown its success in simulating the interaction between fluid and structure with complex boundary geometry. Mittal and Iaccarino[2] classified IBMs into continuous forcing approach and discrete forcing approach based on the way of applying FSI boundary conditions.

Dynamic fracture simulations involve extreme structure deformation and nonlinear material constitutive relation. To avoid the numerical difficulties of distorted grid in Lagrangian method and historical variables recording in Eulerian methods, Harlow[3] proposed the particle-in-cell (PIC) method which discretizes the fluid into Lagrangian particles and computational domain into a uniform Eulerian mesh. Sulsky et al. extended the FLIP PIC method from fluid mechanics to solid mechanics and named this method as material point method (MPM)[4, 5].

The present work combines the concepts of continuous forcing approach and discrete forcing approach, and proposes a novel IBM which can guarantee the boundary velocity conditions strictly at each time step and has no need to keep track of FSI interface anymore. Therefore, the IBM presented here is a promising method for simultaneous simulations of shock-structure interaction and dynamic fracture. And then a method coupling the present IBM with the standard MPM, named CIBMPM, is proposed to simulate the interaction between shock wave and solid structures. The numerical results are in good agreement with several classical shock-structure interaction experiments with fixed or moving obstacle. Finally, the CIBMPM is used to simulate fragmentation driven by detonation and provides a better result than the standard MPM.

Key Words: *Explicit Phase-Field, Material Point Method, Dynamic Fracture, Stability Analysis*

The phase field method is an effective method to simulate arbitrary crack propagation, branching and convergence. Material Point Method (MPM) combines Eulerian method and Lagrangian method, which has advantages in simulation for large deformation problem. The implicit Phase-Field MPM [1][2] has been studied by many researchers for quasi-static fracture problem. However, few work has been presented to study the application of the explicit Phase field on MPM. Due to the iteration in updating phase field of particles, the implicit Phase-Field MPM has poor simulation efficiency and is inappropriate for dynamic fracture problem. On the contrary, explicit phase field is established by importing the viscous dissipation of phase field evolution. And the phase field can be updated with forward difference scheme which avoids the iteration. In this work, A novel explicit Phase-Field Material Point Method (exPFMPM) is introduced for simulation of dynamic fracture problem in elastic media. Many studies have been done in explicit Phase Field Finite Element Method (FEM) [3][4], but few works study the stability of the time integration of explicit phase field. In this work, the effect of particle position and neighbouring cell interaction on stability of exPFMPM is studied. An explicit critical time step formula is obtained based on the system eigenvalues in one dimension, and is then extended to two and three dimensions. And the critical time step formula can also be used in explicit Phase Field FEM. Several tests are performed to verify the critical time step formula. The effectiveness and validity of the exPFMPM method is assessed through several numerical examples (Three-point bending, Dynamic crack branching, ie) for dynamic fracture in brittle materials.

An Immersed MMALE Material Point Method for FSI Problems

Lei Kan, Zixian Sun, Xiong Zhang[1]

[1] School of Aerospace Engineering, Tsinghua University Beijing 100084, China, xzhang@tsinghua.edu.cn

Key Words: *material point method, multi-material arbitrary Lagrangian Eulerian method, fluid-structure interaction, immersed boundary*

The simulation of the fluid–solid interaction (FSI) problem is important for both academic studies and engineering applications. However, the numerical approach for simulating the FSI problems is a great challenge owing to the large discrepancy of material properties and inconsistent description of grid motion between the fluid and solid domains. The difficulties will be further increased if there are multiple materials in the fluid region and large deformation and fracture in the solid region.

Material point method (MPM) provides a powerful tool for modeling extreme deformation and fracture in solid, as well as multi-material arbitrary Lagrangian Eulerian method (MMALE) shows great capability to simulate compressible fluid with multiple materials and shock waves. On the basis of an analogous scheme formulation between the above two methods which consists of Lagrangian variables updating and Eulerian remeshing, an monolithic immersed MMALE material point method is proposed in this work to simulate the FSI problems with compressible fluid and solid of arbitrary constitutive models. In the novel method, the fluid-structure interactions are implicit and fluid-structure interfaces are automatically captured, so that the method could dealing especially well with the FSI problems where structure damage is induced under complex fluid load. Several examples in this paper illustrate the behavior of this novel method.

An Improved Efficient Molecular Simulation Method for Graphene

Key Words: *Molecular Simulation, Dual mesh, Multiple time step, Graphene*

The graphene, as one typical 2D material, has demonstrated its extraordinary mechanical, chemical, electronic and thermal properties. The molecular dynamics (MD) method is a widely used and practical numerical tool for studies on the physical properties of graphene. However, complicated potentials in the graphene system and huge degrees of freedom (DOFs) lead to tremendous computational cost in MD simulation, which limits the applicable spatial and temporal scales. Smoothed molecular dynamic (SMD) method is an efficient molecular simulation method by introducing a set of background mesh and mapping process into molecular dynamics (MD) procedure. A much larger feasible time step can be adopted for the high-frequency modes are suppressed. Inheriting the high efficiency of the original SMD method, we present some improvements for SMD to achieve a proper multiscale mechanical model for graphene simulation in this report.

A dual mesh (DM) scheme is developed according to the lattice structure of graphene, which contains two non-equivalent carbon atoms. Two sets of background mesh are used in DM-SMD and the physical variables of all the atoms in one type will be mapped onto the same mesh, so that the excessive average between different atoms is avoided and the accuracy can be shapely increased. The multiple-time-step scheme is adopted in MD-SMD coupling method. Besides, an adaptive scheme for identifying MD region is developed, where the MD and SMD regions can be automatically alternated during the simulation. The proposed method is validated with several typical examples of single- and multiple-layer graphene and the results demonstrate great accuracy and efficiency.

Key Words: *Material Point Method, Soft materials, Mass growth, Massive deformation, Volumetric locking*

To analyze the growth-induced massive deformations of incompressible soft materials, a material point method (MPM) with a total-Lagrangian formulation was proposed. In this method, the mechanical behavior coupled growth and large deformation is handled within the framework of the MPM based on the multiplicative decomposition of the deformation gradient. A mixed MPM formulation was developed by supplementing a weak-form equation for hydrostatic pressure to avoid the volumetric locking caused by the incompressibility of soft materials. To deal with the cell crossing noise caused by the massive deformation, the total-Lagrangian formulation was further introduced into the mixed MPM. the B-spline basis functions were implemented to the MPM to achieve a high-order accuracy and satisfy the LBB condition. The efficiency and accuracy of the proposed method were demonstrated by several representative two- and three-dimensional numerical examples, such as the free growth of blocks and constrained growth of rings. Some practical problems, including the bending of star and the strain-driven growth of human skin, were further investigated using the proposed MPM to illustrate its ability and potential for evaluating and analyzing the growth phenomena and behaviors observed in nature and engineering. This work was supported by the NSFC (Nos. 12072062 and 12072061), the LiaoNing Revitalization Talents Program (XLYC1807193), Key Research and Development Project of Liaoning Province (2020JH2/10500003) and Fundamental Research Funds for the Central Universities (DUT20LAB203).

Key Words: Residual Stress, Fracture Analysis, PDS-FEM, Tempered Glass

Residual stress field is a self-equilibrium state of stress in the bulk solid materials induced by inhomogeneous inelastic deformations. The residual stress has a great influence on dynamic crack propagation process. The compressive residual stress prevents crack initiation and growth, while the tensile residual stress leads dynamic fracture resulting in the instantaneous and catastrophic destruction.

The dynamic crack growth is accompanied by the release and redistribution of the residual stress. The interaction between the dynamically growing cracks and the residual stress field is complicated enough for preventing us from building effective models, and thereby this phenomenon is left unsolved in the field of solid continuum mechanics.

In this study, we propose a mathematical model and a numerical analysis method for the dynamic fracture in residual stress field. We formulate the dynamic behavior of solid continuum with residual stress field in the context of Particle Discretization Scheme Finite Element Method (PDS-FEM). This formulation enables the evaluation of release and redistribution of the residual stress due to fracture, and the effect of the elastic wave on crack propagation.

By using the proposed model and method, we perform the simulation for the dynamic crack propagation in chemically tempered glass sheets with different residual stress intensity. Our simulation results successfully demonstrated the crack pattern and the crack propagation speed in each tempered glass sheets. These results show that the proposed model and method can be a general framework to simulate the release and the redistribution of the residual stress in the dynamic fracture process.

Key Words: *Smoothed particle hydrodynamics, Penetration, Numerical fracture*

SPH (smoothed particle hydrodynamics) is a gridless Lagrangian technique that is attractive as a possible alternative to the numerical techniques used to analyze large deformation events. In the conventional SPH method, numerical fractures result due to the loss of interactions among particles, which annoys the ability and the accuracy of SPH simulation method. To prevent the numerical fractures, the improved SPH method, which periodically reinitializes (remesh) the particle locations that are being distorted by the serious deformation, and the new particle generation techniques are carried out for the projectile penetration process on aluminum alloy target. Through the numerical simulation, the stress responses of target under different impact velocities are discussed. The relationship between the residual velocity of the projectile and the initial velocity is simulated and analyzed, as well as the failure modes of the aluminum alloy target plate under different impact velocities. The results show that the improved SPH method solves the numerical fracture problem effectively and can describe the physical fracture very well with better accuracy. Meanwhile, the numerical calculation results are in good agreement with the experimental results. The obtained results elucidate the fracture mechanism of target materials under different stress states and provide a theoretical prediction method for experiments, which has certain guiding significance.

Key Words: *Aircraft tyres, Splash water trajectory, Engine flow field, Impact load*

When the aircraft pass through the contaminated runway, its tire splashing may affect the safety of the plane. The side spray of the front landing gear may enter the inlet of the engine and affect the normal operation of the engine. In this paper, the tire splash model under different speed conditions was established by SPH method in LS-DYNA, and the initial shape of tire splash was obtained through simulation. The engine flow field was simulated by CFX, and the velocity information of the engine flow field was obtained. Then the SPH particles in the initial stage of splash water were simplified to droplets and their position, velocity information and engine flow field information are imported into MATLAB. Tire splash trajectories, engine water ingress and impact forces were calculated for different water depths and speeds. Finally, the calculated results are in good agreement with the tire splash test results. The research method can be applied to calculate the splash shape and load of different tire shapes and pollutants, and promote the application of tires with chine configuration, and provide ideas for the morphology and load calculation of the cook-tail water spray.

Key Words: *Nanoconfinement, Water, Machine Learning, Molecular Dynamics*

Fluid-filled porous materials are ubiquitous in nature, such as the shale, soil, bone, plant stem and so on. They also possess wider and wider applications in the modern industry, such as microfluidic channel for cooling, virus detection and so on. Understanding the abnormal change of such fluid-solid system especially with extreme small channel is significant for understanding natural phenomena and applying in industrial engineering. In this work, we focus on the numerical simulation of the water confined in small channel. Firstly, based on the machine learning method, two high-precision water models TIP4P-BG (a conventional four-site water model) and TIP4P-BGT (an advanced model with temperature-dependent parameters) are established. Both the water models exhibit excellent performance with a reasonable balance among the four crucial physical properties. The relevant mean absolute percentage errors are 3.53% and 3.08%, respectively. Subsequently, the controllable deformation of fluid-filled channel through filling with salt water and applying an electric field is examined. With the electric field along the axial direction, the height of CNTs is enlarged by the axial electric force due to the internal ions and polar water molecules. Under an electric field with two mutually orthogonal components, the transverse electric force could further induce the bending deformation of CNTs. Finally, based on the salt water-filled carbon nanotubes, a separation membrane with the adjustable molecular channels by the electric field is proposed. The successive separations and the switch between the high-efficiency and high-purity separation could be achieved only through adjusting the electric field intensity. The reported finding provides a foundation for water-filled small-size channels and provides an insight into the design of nanoscale functional devices. The supports from the National Natural Science Foundation of China (Nos. 11972108, 11672063, 12072061, and 12072062), the LiaoNing Revitalization Talents Program (XLYC1807193), the 111 Project (No.B08014) and Fundamental Research Funds for the Central University are gratefully acknowledged.

Key Words: *crack, peridynamics, stress wave propagation, time-discontinuous formulation, transient problem, contact impact*

A time-discontinuous peridynamic method (TDPD) was developed to accurately simulate the sharp gradient features of the elastic-plastic stress wave propagation and reduce spurious numerical oscillations in transient problems. In this method, the displacement field and the velocity field are interpolated independently using cubic Hermite functions and linear functions in the temporal domain respectively, which are allowed to be discontinuous between the adjacent time steps. The weak form and a new time integration scheme were derived by combining the peridynamic governing equations with the time-discontinuous method. The displacement field is continuous while discontinuous jumps are introduced into the velocity field. The TDPD can effectively characterize discontinuous characteristics of stress and eliminate spurious numerical oscillations that usually appear in the transient solutions obtained by the PD with conventional time integration method for transient problems. Numerical results of many representative problems demonstrated that the TDPD can effectively suppress the spurious numerical oscillations and predict reasonably the crack propagation. The ability of TDPD to accurately predict the initiation and propagation of cracks was also demonstrated through several representative problems involving dynamic fracture. In addition, some 3D contact impact and engineering examples were given, illustrating the broad prospects of TDPD in engineering applications. This work was supported by the NSFC (Nos. 12072062 and 12072061), the LiaoNing Revitalization Talents Program (XLYC1807193), Key Research and Development Project of Liaoning Province (2020JH2/10500003) and Fundamental Research Funds for the Central Universities (DUT20LAB203).

Key Words: Phase-field models of fracture, Gradient damage models, Frictional sliding

The phase-field model has become a popular computational approach for fracture over the past two decades [1]. One of the strengths is its ability to trace propagating fractures without explicit representation of fracture. While this implicit representation facilitates simulation of complex fractures, it obscures explicit properties such as crack opening displacements or stresses resolved on crack surfaces. For this reason, phase-field models have not been extended to frictional sliding, which requires the normal and the tangential stress components on the sliding surface, until the recent work by Fei and Choo [2]. They proposed to decompose the stress at fracture interface into the frictional and non-penetrating components, and iteratively determine the frictional stress using Coulomb's friction criterion. Though their model is able to resolve stresses at interface properly, the mode of fracture propagation is limited to shear (mode-II). In this study, we propose a variational phase-field model with frictional sliding by considering the plastic strain in the sliding direction and the plastic blocking energy in the strain energy as:

$$\Psi(d,\boldsymbol{\varepsilon},\boldsymbol{\varepsilon}^{\mathrm{p}}) = \begin{cases} \dfrac{1}{2}\mathbb{C}(d):\boldsymbol{\varepsilon}:\boldsymbol{\varepsilon} & \text{if open,} \\ \dfrac{1}{2}\mathbb{C}:(\boldsymbol{\varepsilon}-\boldsymbol{\varepsilon}^{\mathrm{p}}):(\boldsymbol{\varepsilon}-\boldsymbol{\varepsilon}^{\mathrm{p}}) + \dfrac{1}{2}\mathbb{H}(d):\boldsymbol{\varepsilon}^{\mathrm{p}}:\boldsymbol{\varepsilon}^{\mathrm{p}} & \text{if in-contact,} \end{cases}$$

where $\mathbb{C}$ is the tangential stiffness tensor, d is the damage, $\boldsymbol{\varepsilon}$ is the strain, $\boldsymbol{\varepsilon}^{\mathrm{p}}$ is the plastic (sliding) deformation, and $\mathbb{H}$ denotes the stiffness degradation by the sliding. We find $\mathbb{H}(d)$ so that it ensures the continuities of the stress and the thermodynamic forces at the open–contact transition. The plastic deformation is computed using Coulomb's criterion as the yield function with an associated flow rule. We demonstrate through examples that our model is capable of capturing the frictional sliding behaviors and unrestricted modes of fracture propagation.

Key Words: Phase field, Hybrid formulation, Staggered scheme, Brittle fracture, Scaled boundary finite element method (SBFEM)

During the last decade, phase field modeling for fracture has attracted much interest in the engineering world because of its impressive capability to handle arbitrarily complicated fracture phenomena also in three dimensions. However, to accurately capture the crack in a diffusive manner, a small positive length scale parameter l_c is required to characterize the width of the regularized crack. The requirement that the element size should be less than half of the length scale renders the method computationally expensive [2]. In this work, an adaptive phase field simulation of fracture in 3D is proposed using a combination of a phase field formulation and the scaled boundary finite element method (SBFEM). Image-based modeling is used to represent the 3D geometries. Taking the 3D image array as an input, the model is automatically decomposed into an octree mesh consisting of regular hexahedrons. The octree mesh is subjected to the 2:1 rule, which determines the size ratio between two adjacent hexahedrons. Hence, the computational effort is reduced by only solving for the unique element configurations.

The SBFEM is used to analyze the balanced, automatically generated mesh. It is a semi-analytical method that facilitates the construction of polyhedral elements where only the faces of the domain are discretized [1]. To achieve accuracy of both the phase field and the elastic analysis, an error indicator based on the SBFEM solution is used to refine the mesh. The staggered solution scheme outlined by Miehe et al. [2] is used to solve for brittle fracture in solids. The hybrid phase field model is adopted, where the phase field variable is assumed to be governed only by the tensile elastic energy, which leads to a linear stress–strain relation [3]. Several benchmark examples are extended to 3D and verified to illustrate the proposed approach.

An Efficient Phase Field Model for Fatigue Fracture

Sikang Yan[1], **Ralf Müller**[2]

ralf.mueller@mechanik.tu-darmstadt.de

Key Words: phase field, fatigue fracture, effcient

The core idea of the phase field model is to represent a discrete, discontinuous phenomenon with a smooth function. For fracture mechanics an additional field variable is introduced to describe the crack. The biggest advantage of the phase field fracture model is its unified framework of the entire crack evolution behavior, including nucleation, propagation, branching, kinking. These phenomena can be covered by one single model. The phase field fracture has been successfully applied to a quasi-statics case. However, there is still a lack of studies on how to efficiently simulate the fatigue fracture phenomenon. In this work, we propose an efficient phase field schemata for cyclic fatigue simulation.

We extend the model from Kuhn and Müller [1] with an additional potential energy term, which provides the necessary driving force for the fatigue fracture evolution. This additional potential is related to the newly introduced damage parameter, representing the damage caused by cyclic fatigue. The additional potential energy is coupled with fatigue parameters from the S-N diagram, which allows the model to generally and elegantly integrate all the influence from the environment to the fatigue propagation behavior. The evolution of the crack field is derived from the total energy with the help of variational principal. The model is consistent with the empirical fatigue propagation property, including the Paris' law and mean stress effect. The model is also robust under complex load simulations.

Traditionally, the fatigue simulation suffers from its huge computational effort since the fatigue crack will only occur after a large number of loading cycles. The cycle number increment influences the computing time of the fatigue simulation and impacts the crack patterns. Thus, the cycle number increment choice is a critical point in the phase field fatigue simulation. We introduce an adaptive cycle increment algorithm, where the cycle number increment is associated with the fatigue damage increment. Our algorithm provides a moderate computing time without losing accuracy compared to the classical computing strategies. Our method is also suitable for parallel computing.

The model has been applied to three-dimensional problems with the real material property. The fatigue life obtained from the phase field model can be verified by experimental and analytical findings.

Fully coupled damage evolution of moisture effects in polymer matrixed composites

The understanding of water penetration, diffusion, and swelling-related strength degradation is critical for assessing the durability of polymer-based composite materials exposed to marine environment. When moisture intrusion and various external loads are concurrently applied to polymer matrix materials, the multi-physical diffusion process, and the correlation with the complex cracking phenomenon is far from been discovered. To approach this uncertainty, we explored fully coupled moisture diffusion, stress redistribution, and damage evolution of composites for revealing complex failure patterns and rules. In our recent work, a thermodynamically consistent moisture diffusion model is established to couple the moisture diffusion and viscoelastic response of the multiphase material. A two-constituent phase-field fracture model is developed to describe the hygroscopic swelling in the matrix and interfacial decohesion within a concise and universal continuum mechanics framework. We also propose a crack filter theory to characterize the fluctuation of moisture flux along with the evolution of regularized discontinuities. A static strength evaluation index is devised to calibrate the moisture resistance of fiber/polymer composites. Based on the strongly coupled scheme, the distinct damage profiles of dry and immersed composites were captured in line with experimental observations. For the first time, interactions of moisture diffusion with the complex cracking in composites are elucidated through simulations, thus providing new insights into the coupled damage mechanism of polymer composites and facilitating microstructure design to enhance its performance in ocean environments.

Key Words: fracture,desiccation, phase-field, heterogeneous materials, random fields

The fracture of thin films bonded to compliant substrates presents a number of challenges to model-based simulations. Typically, the films are assumed to be subjected to a bi-axial state of stress that arises due to a mismatch in material properties with the underlying substrate. The film can quickly become ovestressed, giving rise to pervasive crack nucleation and growth. Our current work looks to build on recent efforts studying the influence of bulk and fracture properties on crack patterns in these systems using a cohesive-based phase-field model of fracture [1]. In particular, we examine results obtained using an adaptation of a recently developed phase-field model that employs a stress envelope to control crack nucleation [2]. We examine the sensitivity of the simulated crack patterns to variations in model parameters responsible for both nucleation and growth. Results are compared to our previous studies in which crack nucleation was governed entirely by energetics.

Key Words: Phase-field, micromorphic, fracture irreversibility, variational inequality , AT1, AT2

The phase-field fracture model has emerged as a promising alternative to discrete fracture models (e.g., cohesive zone and extended finite element models) owing to its straightforward handling of of complex fracture topologies (crack branching, kinking and merging) and circumventing the need for remeshing techniques. In this model, the fracture is represented by the phase-field, which, along with the displacement field are the primary nodal unknowns. The enforcement of the fracture irreversibility constraint in conjunction with higher regularity requirements on the phase-field (H1 space) results in a 'global' variational inequality problem. In this contribution, a micromorphic phase-field fracture model [1] is proposed. In this model, the micromorphic variable regularizes the fracture problem, while the phase-field is transformed into a local quantity. As a consequence of the latter, the enforcement of the fracture irreversibility constraint is relatively easier to treat in a computational framework. The energy functional for the micromorphic phase-field fracture model is obtained upon replacing the phase-field in the gradient term with a micromorphic variable, followed by penalizing the difference between the phase-field and the micromorphic variable. Both AT1 and AT2 brittle fracture models have been addressed in this contribution. Unlike the history variable approach, the micromorphic AT1 variant does not require a fictitious initial energy to represent the intact material state. Adopting benchmark problems, a performance assessment is carried out whereby the iterations required for convergence, the choice of the penalty parameter, and possible convexification measures (time-lagging, extrapolation) are addressed.

Microstructure sensitive fatigue crack growth in anisotropic polycrystals

Hirshikesh[*,1], **Nishant Prajapati**[1], **Daniel Schneider**[1,2] **and Britta Nestler**[1,2]

[1]Institute for Applied Materials - Computational Materials Science (IAM-CMS), Karlsruhe Institute of Technology, Karlsruhe, 76131, Germany.
[2]Institute of Digital Materials Science (IDM), Karlsruhe University of Applied Sciences, Moltkestrasse 30, 76133, Karlsruhe, Germany.

Key Words: Fatigue crack growth, Multiphase-field method, Polycrystals, Grain boundary strength, Material anisotropy

Accurately quantifying the resistance of mechanical component to fatigue crack growth is an essential part of predicting component lifetimes. For a polycrystalline material where each crystal has a different orientation, mechanical characteristics (e.g. Young's modulus, Poisson's ratio, fracture toughness), and associated anisotropies, fatigue crack growth prediction becomes extremely complicated and challenging. To this end, a multiphase-field model for simulating fatigue crack growth in brittle anisotropic polycrystal is proposed which utilises recently introduced [1] fracture toughness reduction as the measure to account for rate- or cycle-dependent crack growth phenomena. The formulation of phase-dependent fatigue strength, which accounts for differing fatigue properties of different crystals, is a significant and innovative component of this research. The multiphase-field formulation also allows to mimic different grain boundary energy (e.g. weaker or stronger grain boundary) of the polycrstalline material [2]. The proposed model is capable of simulating complex crack trajectories under fatigue loading in the complete parameter space, including inter- and transgranular fracturing, where distinct grains have different fatigue properties and preferred planes for crack formation based on fracture toughness anisotropy. Several two-dimensional benchmark problems with multiple cracks are addressed to showcase the capabilities of the proposed model for fatigue crack growth.

Key Words: Parallel computing, FE method, Phase-field models, Fracture mechanics, Preconditioning

Phase-field models (PFMs) are widely used to model fracture in solids. Similar to continuum damage mechanics models, material degradation is described via a scalar-valued phase/damage field ranging from zero (sound material) to unity (fully broken material) and submitted to irreversibly conditions. Damage evolution is modeled by solving a Helmholtz-like damage diffusion equation. The final boundary value problem involves finding a vector-valued displacement field and a scalar-valued damage field that fulfills the non-linearly coupled momentum balance (equilibrium) and damage diffusion equations. Resolution strategies involve either a staggered or a monolithic approach to solving the final boundary value problem. In this work, attention is focused on solvers for the "hybrid" PFM by [1], with the primary objective of developing effective finite element (FE) implementations and to perform large-scale fracture mechanics simulations. Indeed, very refined meshes are needed for solving PFMs in the FE framework for practical problems of interest. Large non-linear systems of coupled equations have to be solved, which makes using these models in large-scale applications a tiresome task due to the high computational workload. Domain decomposition approaches can be used to subdue these issues and considerably decrease computational workload. The computational domain is partitioned into thousands of sub-domains, and the FE linear systems concerning the PFM equations are then concurrently assembled and eventually solved using parallel Krylov subspace methods. Within this contribution, we implement and discuss two ways of setting up domain decomposition parallelism for a hybrid PFM [2] under the distributed computing framework. Particularly, a monolithic FE strategy is compared to a staggered FE strategy. These two methods lead to different matrix sparsities; as such, to yield a fast and robust parallel solver, different preconditioning/parallelization strategies must be applied. Besides presenting the two distinct ways of setting up parallelization for the considered PFM, this article presents a detailed comparison of the performance, scalability, and efficiency of the two methods at massively parallel scales. Overall, this allows for rapid solving non-trivial fracture mechanics problems with millions of unknowns [2].

A large class of solar cell wafers, an integral component of the renewable energy industry, are made of silicon crystal that falls under cubic symmetric class of anisotropic materials. Such a material exhibits, along certain planes, a complicated four-fold symmetry in its elastic parameters as well as in its fracture toughness. Large difference in the amount of energy required for crack propagation along two salient crystallographic orientations gives rise to strong and weak directions, thus leading to strong anisotropy. Additionally, due to cubic symmetry, the two weak directions along which the crack tends to kink are symmetrically located, thus leading to zigzag or saw-tooth crack patterns.

In this work, we follow the well-established phase-field approach for fracture to study cracking in silicon. In particular, we build upon and extend the fourth-order phase-field approximation introduced in [1] containing the second gradient of the phase-field variable in its regularized energy functional in addition to the usual first gradient. A thorough analytical and numerical analysis of the resulting formulation is presented. Furthermore, lack of convexity in the minimization of the coupled phase-field and elastic energy potentials in the isotropic setting gets more severe in the cubic symmetric case given that its fracture toughness, a component of the phase-field energy functional, alone is non-convex. To address this, we transition from a deterministic to a stochastic setting by introducing perturbations in the form of a random field in the anisotropic phase-field energy functional to capture solution non-uniqueness [2]. Such a stochastic phase-field model describes multiple crack paths and their probabilities. The additional insight into the solution behavior, however, requires a larger computational effort. Lastly, results from an experimental campaign undertaken to understand anisotropic fracture in silicon and to calibrate model parameters are discussed. The outcome of this work is hence a well-assessed stochastic phase-field anisotropic module that can be employed to investigate four-fold symmetric fracture anisotropy for complex applications.

Key Words: Phase-field fracture, Humerus Fracture, Finite Cell Method

Fracture of the proximal humerus as a result of a fall on an outstretched arm is a common injury among the elderly population. While numerical simulation of bone fracture is a challenging task due to the complex and heterogeneous structure of bone, it is important to advance our understanding of this frequent injury. In this contribution, we present a numerical framework for the simulation of fracture in human bones which is based on a combination of a phase-field model for brittle fracture with the Finite Cell Method (FCM) and adaptive refinement. As presented in [4, 3], integration of the FCM [2] as an embedded domain approach enables the efficient simulation of complex geometries without the need of generating boundary conforming meshes. Multi-level *hp*-refinement allows for a locally refined mesh which dynamically adapts to the crack path. In order to capture fracture in human long bones, the phase-field model was adapted to account for a spatially varying critical energy release rate following [5].

The validity of the phase-field model is discussed based on experimental data of three humeri which were fractured at the anatomical neck [1]. The qualitative comparison of fracture patterns shows very good agreement of computed crack paths with experimental results. Digital Image Correlation (DIC) measured strains as well as experimental failure loads are compared against the numerical computations. The results demonstrate the potential of the proposed framework to simulate fracture in human humeri, and motivate us to attempt a generalization of the model to vertebrae, which will be reported on as well.

Key Words: Crack phase-field formulation, Ductile fracture, Damage variable, Flow rule, Evolution law

This study presents a variationally consistent formulation for crack phase-field (PF) modeling of ductile fracture. First, we review the existing models [1, 2, 3], in which emphases are placed on the plastic driving force [1, 3] and degrading fracture toughness [2, 3] that enable PF models to represent the damage evolution in elastoplastic materials. Our attention is also focused on the use of either effective or nominal quantities in the yield function [4] as a new perspective in PF modeling.

Based on these discussions, the formulation of the proposed model is readily made. The constitutive work density consists of stored and dissipated components, in which damage variables are separately introduced for elasticity and plasticity in order to derive variationally consistent evolution laws for plasticity and damage as the stationary conditions of the supremum problem of the dissipative potential related to the constitutive work density. Since such a variational structure of evolution laws has been overlooked or not considered in previous studies, the relevant consideration would provide a new perspective for the crack phase-field community. After the governing equations are derived from the optimization problem within the continuum thermodynamics framework, numerical examples are presented to demonstrate the characteristic feature of the proposed model.

Key Words: *Data assimilation, Material modeling, Finite Element Method*

Application of aluminum alloy sheets to automotive components is effective in reducing weight of automotives. However, formability of aluminum alloy sheets is lower than that of steel sheets. To compensate for this disadvantage of formability, it is effective to improve forming techniques of aluminum alloy sheets by understanding the forming limit of aluminum alloy sheets using finite element-based sheet metal forming simulation. In order to improve the accuracy of sheet metal forming simulation, it is necessary to calibrate a yield function and its parameters (i.e., material model) that accurately describes elastoplastic deformation behavior of aluminum alloy sheets. So far, a combination of digital image correlation (DIC) with finite element model updating[1] was proposed as a promissing method to calibrate the material model with high accuracy. However, to the our best knowledge, no material modeling method that can evaluate uncertainty of experimental data has been reported. Therefore, the purpose of this study is to develop a new material modeling method using the data assimilation theory based on Bayesian inference[2] that can evaluate the uncertainties of both experimental and simulation data. In this talk, we present the calibration results of Yld2000-2d yield function[3] using the computationally effcient data assimilation method named as DMC-BO method[4] and a full-field strain measurement by DIC method for a 5000 series aluminum alloy sheet.

Key Words: *ZX10 Magnesium alloy sheet, Crystal Plasticity Modeling, Work Hardening, Twinning, Detwinning*

Magnesium (Mg) alloy sheets are expected to be used as light-weight materials for structural components because of their low density and high specific strength. However, their press formability at room temperature is poor due to the strong crystal anisotropy of the hexagonal structure and the strong basal texture especially observed in AZ series rolled Mg alloy sheets. Recently, ZX series Mg alloy sheets have been developed that weaken the basal texture, thus improving press formability at room temperature [1].

The plastic deformation behavior of a rolled Mg-1.5mass%Zn-0.1mass%Ca (ZX10Mg) alloy sheet was examined in our previous study [2]. It was shown that the in-plane anisotropy of the stress-strain curve was more pronounced under tension than that under compression. Moreover, the tension-compression asymmetry was more pronounced in the rolling direction than that in the transverse direction. In the present study, a crystal plasticity finite-element method was used to study the mechanism of the abovementioned plastic deformation behavior.

A crystal plasticity finite-element method program developed by the authors [3] was used in this study. The material parameters were determined to obtain reasonable fits in the stress-strain curves under tension and compression in the rolling direction. The simulation results were compared with the experimental results of the stress-strain curves under tension, compression, and reverse loading in different directions, and they were qualitatively in good agreements with the experimental results, verifying the model. The simulation results showed that twinning was active not only under compression in the rolling and transverse directions but also under tension in the transverse direction. It was presumed that the difference in twinning activity under tension between the rolling and transverse directions resulted in the abovementioned in-plane anisotropy and the tension-compression asymmetry. In the presentation, results of reverse loading tests will also be discussed.

Material Model Calibration using 3D-DIC Measurement and Bayesian Data Assimilation

Sae Sueki[1*], Akimitsu Ishii[1], Eisuke Miyoshi[1] and Akinori Yamanaka[1]

[1] Tokyo University of Agriculture and Technology, 2-24-16, Naka-cho, Koganei, Tokyo, 184-8588, Japan, a-yamana@cc.tuat.ac.jp

Key Words: *Data assimilation, Inverse material modelling, Digital image correlation*

Accurate prediction of material deformation behaviors using finite element simulation is important in various industrial fields. In order to improve the predictive accuracy of the finite element simulation, material models including a strain hardening model, a yield function, and their parameters have to be calibrated based on experimental data. In particular, the calibration of material model based on three-dimensional (3D) observation of material deformation behavior is required. For decades, various methodologies for the inverse material modelling using full-field measurements such as digital image correlation (DIC) have been developed [1, 2]. To perform the inverse material modelling, the authors propose to use Bayesian data assimilation (DA) that enables the estimation of unknown parameters and unobservable states of materials by integrating experimental data with the finite element simulation based on the Bayesian inference framework [3]. Although uncertainty quantification in the conventional inverse material modelling remains a challenging issue, DA allows us to evaluate the uncertainty of the identified material model by evaluating covariance of probability density functions of experimental and simulation results. In this study, we propose a new methodology for the inverse material modelling using the ensemble-based four-dimensional variational method (En4DVar) [4, 5] and the full-field 3D-DIC measurement which is one of the most versatile and easiest methods to obtain heterogeneous displacement- and strain-fields over the entire surface of material. By integrating the experimental data obtained by the full-field 3D-DIC measurement to the finite element simulation using En4DVar, it is expected that the material model can be more accurately calibrated. We validate the proposed inverse modelling method by applying it to the estimation of strain hardening parameters and the anisotropy parameters of yield functions (e.g., the Hill and Yld2000-2d yield functions) based on the 3D-DIC measurement of an aluminum alloy specimen subjected to the uniaxial tensile test. In this talk, we will present the result of inverse material modelling using the proposed method.

Key Words: *9 Fracture, Gurson model, shear loading, low triaxiality*

Anchored connections in downhole operations in the Oil & Gas industry are formed by the indentation of tools' setting teeth on the internal surface of deep-well casings. These connections are expected to support loads that are in the longitudinal casing direction, loads include the anchored tools self-weight as well as forces imposed by connected equipment. The loads are supported by the anchored connection shear strength. The scale of the setting teeth is in the range of 1 millimeter, which implies that failure zone around them is in the sub-millimeter scale. Motivated by the non-proportional localized loading on the failure zone through the thickness of the steel casing, we propose the calculation of the strength of this connection using a shear-extended Gurson model.

The successful use of the shear-extended Gurson model is contingent on the model calibration to represent the material response. Therefore, a suite experimental tests were performed to characterize the material failure in different multi-axial loading regimes. The experimental testing results were used to inform the model calibration. The calibrated model is used to assess the anchored connection strength, a two-dimensional plane strain idealization is used. First, the formation of the anchored connection is represented by the indentation of the setting teeth into the casing substrate. This stage captures the localized deformation in the casing surface. Then, a shear loading is applied on the teeth to resemble the applied loads. The dependence of the connection's shear strength on the indentation depth is investigated for an increasing number of setting teeth. The modeling leads to novel insights on the response of the shear-extended Gurson model under combined multi-axial loads. In addition, it leads to the establishment of general trends in the relationship between shear strength and indentation force.

A Multi-Scale Probabilistic Model for Progressive Failure Assessment on Woven Composite Laminates

Aoshuang Wan[1*]

[1] School of Aerospace Engineering, Civil Aviation University of China, Tianjin, 300300, China, aswan@cauc.edu.cn

Key Words: *Woven composite, Multi-scale, Progressive failure assessment, probabilistic model*

Woven composites have been increasingly applied in aerospace, military and transportation due to their excellent specific stiffness, specific strength, impact resistance and fracture toughness[1]. Reliable evaluation on multi-scale mechanical response and failure process of woven composite structures with the aid of numerical tools remains a challenge and hot issue owing to their complex woven fabric geometry. This paper proposed a multi-scale probabilistic model for progressive failure assessment on woven composite laminates considering the stochastic nature of constituent material properties and random distribution of fibers. Three-scale finite element models with randomly distributed material properties are established to study the mechanical response of woven composites, including microscopic representative volume element (RVE) model of yarn, mesoscopic RVE model of woven composite lamina and macroscopic model of notched woven laminates. Multi-scale failure criteria for woven composites are developed to account for physical failure modes at fine scale and phenomenological failure law at coarse scale. Integrating Monte-Carlo method with progressive failure assessment model, repeated simulations at three scales are performed to obtain the probabilistic distribution of mechanical properties and progressive failure process of woven composites. Good agreement between numerical results and experiments has been achieved.

Efficient computational Multiscale Method for Polymer solids and Structures under Large number of Cycles

Darith Anthony Hun[1], **Mohamed Haddad**[1] **and Issam Doghri**[1]

[1] Université Catholique de Louvain, 1348 Louvain-La-Neuve, Belgium, darith.hun@uclouvain.be

Key Words: Laplace-Carson inversion, high cycle simulation, periodic basis, polymer structures

In this work, a computational method is proposed for viscoelastic (VE) and viscoelastic-viscoplastic (VE-VP) polymer solids and structures subjected to large numbers of loading cycles. The proposed method uses the Laplace-Carson Transform (LCT), extended for periodic response.

For linear VE materials, the methodology is based on the decomposition of the VE problem into transient and periodic sub-problems invoking the superposition principal. Each one is solved independently in Laplace-Carson domain. Then the transient response in time is recovered by LCT inversion using Schapery's collocation method. For the periodic part, sinusoidal functions decomposition is formulated, and the Newton-Gauss algorithm is employed for the numerical inversion. First, the accuracy of the proposed method is assessed on some known time functions. Next, the procedure is tested for VE structural problems (10k cycles, 2D structures, different boundary conditions) and the results are compared to those of reference solutions computed directly in the time domain. The comparison in local scale (displacement, strain and stress at various points) and macro scale (global energy indicator) shows excellent accuracies. The speedup factor (32 for 10k cycles) increases significantly with the number of cycles.

The proposed method has been extended to thermoplastic polymer solids and structures exhibiting coupled VE-VP material response. A multiscale approach in space and time was developed, taking into account a heterogeneous microstructure (VE matrix, VE-VP weak spots and process-induced porosity) and two time scales: macroscopic (at the end of each cycle) and microscopic (within each cycle). Numerical results showing the accuracy and efficiency of the method on structural problems are presented. This opens the door for an efficient multiscale modeling and prediction of high cycle fatigue.

Key Words: *CFRP, micromechanics analysis, deep neural networks, failure criteria*

Carbon Fibre Reinforced Polymer (CFRP) composites are currently being utilised in many engineering applications due to their excellent design flexibility and high specific strength and stiffness. However, the failure of composites is difficult to predict due to the complex coupling effects of different damage modes under combined stress states. Failure criteria play a vital role in the design of composite structures. The lack of comprehensive experimental data for the validation of computational failure models, especially for composite structures subjected to multiaxial loadings, has led to highly conservative designs.

Numerical modelling is widely used in industry to accelerate composite design and aid failure prediction, using a suite of computational tools including the finite element method, the phase field approach, discrete element method, or peridynamics. Currently, micromechanics-based 3D Representative Volume Elements (RVEs) are widely used to analyse the microscale failure mechanisms of composite materials which lead to macroscale (structural) failure. In this paper, high-fidelity finite element-based 3D RVE models were developed to analyse the failure mechanisms of IM7/8552 CFRP unidirectional (UD) composites subjected to biaxial loading conditions via periodic boundary conditions. The Drucker-Prager plastic damage constitutive model, and cohesive zone model, were utilised to simulate the mechanical response of the matrix and fibre-matrix interface respectively. Fibres were assumed to be transversely isotropic, elastic and brittle, where fibre failure was predicted by the maximum principal stress criterion. After validation of the RVE models with experimental tests under biaxial loading conditions, numerical simulations of other biaxial cases were conducted. Due to the transverse isotropy of the cross section of UD lamina, nine out of fifteen loading stress combinations were selected. For the generation of failure points, defining a failure envelope, an average of ten loading cases were considered for each selected biaxial stress combination. In order to generate enough data from the obtained numerical results, probabilistic failure distributions were attributed to the data points. Normal and Weibull distributions were used to describe the scattering of biaxial data with failure probabilities deduced from off-axial experiments and the mean failure surface determined using a univariate spline function. Because of the limitation of available experimental data, obtained failure envelopes were assumed to be self-similar which meant the failure envelope contracted or expanded with different failure probabilities and shared the same scattering factors with the ones from the experiments. A database, containing half a million samples was collected, and each sample had six stress components as input and provided a probabilistic failure output. A deep neural network with four hidden layers was used to construct the failure criterion for the lamina. The number of neurons in each layer was 128 after parametric study. Good agreement between the true values and predicted values was achieved.

Key Words: *fracture, R-curve, FEA, VCCT*

Full-scale structures with notches are sometimes stronger than expected on the basis of Linear Elastic Fracture Mechanics because of the existence of R-curves. An R-curve describes an increase in fracture energy with increasing notch length, which is important for the prediction of notched failure of composite structures. R-curves can be implemented in different Finite Element (FE) modelling schemes such as Cohesive Zone Models [1], High-fidelity Finite Element Models [2] and Continuum Damage Mechanics Models [3]. It is also desirable to implement R-curves using a simple FE modelling method to reduce computational costs when modelling large composite structures. One popular method for modelling cracks is the Virtual Crack Closure Technique (VCCT) based on linear elastic fracture mechanics. VCCT for Abaqus [4] provides extensive fracture mechanics capabilities and can be used as a predictive tool to better analyse the crack propagation behaviour in composite structures. The current study aims to take account of R-curves for trans-laminar fracture of carbon/epoxy laminates using Abaqus VCCT with its nodal energy rate option. This enables the specification of a list of critical strain energy release rates to a set of nodes along the crack surface, effectively implementing an R-curve. The linear R-curves implemented in this study was initially measured by Xu, et al. [5] and extrapolated where data is not available. The Abaqus VCCT predicted load-displacement response will be verified by experiments.

In recent years, advanced fiber-reinforced composites have been increasingly applied in aviation and aerospace instead of conventional metallic materials due to their superior properties such as high strength, stiffness, and low weight. Particular attention must be paid to model the delamination initiation and propagation to ensure the composite structures do not fail prematurely. The most important feature for implementing composite materials in aviation is their behavior on dynamic loads and resistance to fatigue. However, there is a lack of numerical procedures to accurately predict the delamination growth in complex composite structures under fatigue loading. Therefore, it is essential to find the response and behavior of aircraft composite structures under fatigue loading. In this study, the progressive damage modeling-based approach (Cohesive zone approach) included in ABAQUS is adopted in conjunction with the Paris law to analyze the delamination in composite aircraft structure under the operating load spectrum fatigue loading. FEA modeling is verified through comparison with experimental specimen data [1], and the verified FEA model is applied to the composite aircraft tail wing structure. In this case, a Monte Carlo simulation is performed by building a response surface model considering the uncertainty of the parameters. Through this process, the risk according to each flight time can be quantitatively evaluated, and the inspection interval is optimized by selecting the combination with the lowest number of repeated inspections within the conditions that meet the permitted risk criteria.

Mesh independent modelling of tensile failure in composite laminates using mixed-time integration in explicit analysis

Jagan Selvaraj[1*], Luiz F. Kawashita[1] and Stephen R. Hallett[1]

[1] Bristol Composites Institute, University of Bristol, BS8 1TR, UK
jagan.selvaraj@bristol.ac.uk

Key Words: *Cohesive zone modelling, Finite element analysis, Composites*

Discrete crack modelling involves representation of cracks in a material as geometric discontinuities. Within a finite element framework, mesh independent crack modelling is performed such that crack propagation is not restricted to element boundaries and can propagate across a mesh. In composite laminates, matrix cracks are usually the first to appear and drive delamination due to stress concentration. Although delamination between plies is restricted to element boundaries in a mesoscale model, transverse matrix cracks in non-fibre aligned meshes are not and thus require mesh independent modelling. A set of non-linear events following matrix crack onset and delamination growth result in the final failure of a laminate along with or without fibre failure. Explicit time integration is preferred to model this nonlinearity numerically and the challenges in modelling are (i) reduction in the stable time increment of an analysis following element splitting and the corresponding increase in computational cost and (ii) challenges in remapping of integration domains and initiation of cohesive segments. To solve the first problem, a mixed time integration or subcycling [1] is introduced adaptively following element splitting. The second problem is solved by initiating cohesive segments between the newly initiated elements with minimal disturbance to the surrounding stress state by nodal force balance. Application of mixed-time integration to crack modelling requires extensive analysis and this work is focussed on the challenges in the implementation, the effects of assumptions involved in subcycling and the computational benefits. Suitable numerical examples are demonstrated by modelling tensile failure in composite laminates. Linear solid elements are used in unstructured meshes where the crack geometry does not align with the initial mesh. Tensile failure of an angle-ply laminate and a quasi-isotropic laminate with an open hole is modelled. Crack initiation is performed adaptively along with mixed time integration. Good correlation with experimental results in terms of failure patterns and failure stress is obtained. Following this, the challenging case of tensile failure of a laminate with an embedded wrinkle is also modelled using the introduced framework. The analysis is numerically stable with 240 matrix cracks and 23 delamination planes successfully modelled to predict a very similar failure stress to experimental results [2].

Key Words: *Fatigue Life, Composite Biomaterials, Constitutive Modeling, Cyclic Creep*

Introduction. Soft connective tissue is a fibrous composite that is susceptible to injury from single high-magnitude static loads and repetitive low-magnitude fatigue loads. While many constitutive formulations have been developed to model static failure in soft tissue, a modeling framework has not been established for fatigue failure. The identification of a constitutive framework that can describe and predict soft tissue fatigue failure could help explain this poorly understood failure phenomena and advance the prevention and treatment of fatigue injuries [1]. Here we determined the feasibility of using a visco-hyperelastic damage framework to simulate high cycle fatigue failure in soft fibrous tissue.

Methods. Cyclic creep data from six uniaxial tensile fatigue experiments of human meniscus was used to calibrate the specimen-specific material parameters for a visco-hyperelastic damage model with discontinuous damage (strain energy-based failure criterion) subjected to force-control loading. The optimization of the calibrated material parameters was performed in a custom MATLAB code that simulated a single volumetric element subjected to force-controlled loading. The quality of model fit was quantified using normalized root mean square error. The sensitivity of the model simulations to changes in material parameter values was evaluated, and a validation study was performed by evaluating the model's ability to simulate the stress-strain curve of monotonic uniaxial tensile experiments (static failure).

Results. The model was able to successfully simulate all stages of cyclic creep, including steady-state creep and the rapid progression to tissue rupture for experiments that failed between 150 to 400,000 cycles (NRMSE = 2.4 ± 2.6%). Mathematically, damage propagated under constant cyclic stress due to time-dependent viscoelastic increases in tensile stretch that in turn increased strain energy. Our results implicate viscoelasticity as a fundamental regulator of fatigue failure in soft tissue, where our sensitivity study found that tissue with slow relaxation times is more resistant to fatigue injury. In a validation study, the visco-hyperelastic damage model was able to simulate characteristic stress-strain curves of pull to failure experiments (static failure) when using material parameters curve fit to the fatigue experiments.

Conclusion. For the first time, we've shown that a visco-hyperelastic discontinuous damage framework can model cyclic creep and fatigue failure in soft fibrous tissue. A clear benefit of this approach is that constitutive equations for discontinuous damage and viscoelasticity are well established and are available in commercial and open source finite element solvers [2]. Importantly, our results demonstrate that this modeling framework may enable the reliable prediction of both fatigue and static failures from a single constitutive formulation.

Key Words: *Z-pin, Delamination, Finite Element Analysis, Cohesive Element*

Z-pinning entails inserting small rods through the thickness of fibre-reinforced polymer composites, and it has been proved to be very effective on mitigating interlaminar disbond (delamination) for composites. Almost all research on the mechanical applications of Z-pins focuses on delamination growth in flat panels [1], while delamination could also be a dominant failure mode in a curved laminate structure when subjected to a bending moment. Ju et al. [2] experimentally demonstrated that it is feasible to increase the curved-beam bending strength by inserting grooved stainless-steel Z-pins in the curved area. In the current work, further experiments to verify whether carbon-fibre composite Z-pins also show this enhancement effect when inserted in curve laminates are being undertaken. Furthermore, computational simulation is required to have a comprehensive understanding on the failure mechanisms of Z-pinned curved laminates subjected to four-point bending.

A meso-scale Abaqus/Explicit® 3D Z-pinned curved laminate model was built in this study. The model was created with a versatile mesh generation code, which was written by combining Python and MATLAB®. The user is able to control almost all the input parameters, such as pin number and spacing, stacking sequence, fibre orientation, roller diameter and position, material properties and interface definitions, etc. An eye-shape resin-rich zone is modelled around each pin. Cohesive elements were inserted between different-angle plies to simulate delamination. Node-to-surface tie constraints were defined between interlaminar cohesive layers and their adjacent plies. The pin/laminate interface was modelled with a user defined constitutive cohesive-friction law, which was implemented by a VUINTERACTION subroutine[3]. In the subroutine, a modified Coulomb friction formulation, which was proposed by considering the Z-pin surface roughness, was coupled with a bilinear cohesive formulation to simulate pin/laminate bonding and pin/laminate frictional pull-out [3,4]. The simulations are firstly verified against experiments in terms of both global and local observations. The high-fidelity modelling technique is then used to unveil the bridging mechanics of discrete through-thickness reinforcement in curved laminates when subjected to an ambient through-thickness tensile stress field.

Key Words: *CMCs, C/SiC, Damage Evolution, Meso-model, Uncertainty*

C/SiC ceramic matrix composites (CMCs) are one of the most important materials for aerospace thermal protection structures due to their excellent properties, such as high temperature resistance, high specific strength and high specific modulus. However, the complex manufacturing process leads to the inevitable emergence of initial defects in the matrix and oxidative damage of the fiber bundles, which may result in the complicated microstructure of the materials and significant decrease in the mechanical properties of C/SiC composites. Hence, it is of great importance to find the internal damage behaviours of C/SiC composites and to construct the suitable mechanical constitutive of materials for the structural analysis and design.

In this paper, the probability distributions of mechanical properties for 2D-C/SiC composites under the uniaxial tensile are focused on. The representive volume element (RVE) model of 2D-C/SiC composites in meso-scale was established by TexGen, and the periodic boundary conditions were imposed to predict the initial elastic properties of the composites. Uncertainties of the tensile strength and elastic modulus were considered to model the random features of fiber bundles and matrix and to quantificate the uncertainty propagation of mechanical performance of composites. The input probability distributions and their parameters are obtained from statistical data of experiments, and normal and Weibull distributions are applied to modulus and strength, respectively in this research. The progressive damage analysis under uniaxial tensile was conducted with finite element method (FEM) through user-defined subroutine considering multi-failure modes of fiber bundles and matrix, whose results show good consistency with those of the experiment. 100 repeated FEM simulations were performed with independent random sampling of input parameters, to characterize the randomness of mechanical properties of materials reasonably, which demonstrates the validity of the proposed model for performance prediction and structural analysis of 2D-C/SiC composites inconsideration of initial uncertainties.

Key Words: *Carbon fibers, Fatigue, Finite element analysis, Fractography, Life prediction*

Fatigue life is one of the most important strength factors to be considered in the equipment design. For metallic materials, a design method has been established to determine the allowable stress obtained from specimens and to complete the design after confirming that the stress is below the allowable value, as shown in the technical standard for high pressure vessels.

In the case of carbon fiber-reinforced plastics (CFRP), fatigue design has not been established to guarantee the long-term reliability required for application to strength members, because the complex fracture processes due to the microstructure of CFRP have prevented the application of established methodologies for metallic materials. To ensure the long-term reliability of CFRPs, it is necessary to perform a long-term endurance test that imposes actual loads on actual parts, as executed in the design verification test of the high-pressure hydrogen storage tank for fuel cell vehicle. In order to break away from this situation, it is necessary to establish a fatigue life evaluation method for CFRP equipment with highly versatile parameters.

The authors proposed the fatigue life evaluation method of unidirectionally (UD) reinforced CFRP specimens from the fatigue test results of the pure resin constituting CFRP [1]. Based on the assumption that the fatigue life of CFRPs is governed by that of its matrix resin, the interfacial normal stress (INS) obtained from micro-scale stress analysis is used as an evaluation index. INS, which was proposed by Hojo et al. [2], is defined as normal stress on a plane perpendicular to a line of minimal length that connects the center axis of carbon fibers.

In this study, we evaluate the applicability of the INS evaluation method to CFRP laminated specimens, since the previous study has been performed only for UD specimens. Three types of laminated specimens with different lamination configurations ($[0/30/-30/90]_s$, $[0/45/-45/90]_s$, and $[0/60/-60/90]_s$) were prepared and fatigue tests were conducted in advance.

Key Words: *CFRPs, Self-healing, Electrospinning, Open hole, Fatigue, Tensile, Diels-alder, GNPs, numerical simulation*

Diels-alder (DA) based polymers exhibit healing functionalities on polymer level due to their thermal reversible nature [**1**]. In the current investigation, self-healing (SH) resin based on Diels-Alder (DA) reaction mechanism was integrated into high performance aerospace carbon fiber reinforced plastics (CFRPs) by electrospinning process technique (solution and melt electro-writing process). The effect of the selected SHA into CFRPs was further assessed. More precisely, open-hole reference and SHA modified CFRPs (containing GNPs at the amount of 1 wt %) coupons have been tested under quasi static tensile and tension-tension fatigue loading conditions. Their stacking sequence was $[45/-45/0/90]_{2S}$ and had similar fiber volume fractions. The structure of the experimental test campaign organized and realized for the needs of the current work as follows. The work started with tensile tests to pristine and open hole CFRPs coupons (for both reference and modified) in order to identify the apparent modulus and the ultimate tensile strength (UTS). Also, we had to investigate whether the introduction of the SHA into the structure of CFRP has any knock down effect to the mechanical properties. Then, the fatigue procedure followed and divided into three stages. The first stage investigates the fatigue life performance of reference and SHA modified CFRPs at continuous fatigue loading conditions. In the second stage, the fatigue experiments for both reference and modified composites were paused every 10 k cycles in order the damage evolution within the composite to be monitored using c-scan inspections. Finally, during the third stage the same route as in the second study level was followed, together with the activation of the healing process after each interruption of fatigue loading. Thus, this investigation thoroughly investigates the effect of the SHA healing capacity on the fatigue life performance of CFRPs. All tests were conducted under load amplitude control at 0.8 of UTS of reference CFRP, at R=0.1 and loading frequency f =5Hz. According to quasi static experimental results, it was shown that the incorporation of the SHA did not significantly deteriorate the in-plane mechanical properties of the entire composite. The activation of the healing functionality of modified composites at certain number of fatigue cycles revealed damage recovery based on c-scans (macroscopically) which further improved the mechanical performance of the composites. For all fatigue tested material sets a three-stage pattern of stiffness degradation was observed. Furthermore, numerical modelling and simulation of damage tolerance and healing capability of these CFRPs were performed via the development of appropriate cohesive zone models. The constitutive behavior of the cohesive zone was defined by the traction–separation relation derived from laboratory tests. The variation of the traction-separation relation after healing is directly related to the nature of SH material.

Key Words: *Self-healing ceramics, Finite element analysis, Oxidation kinetics, Constitutive model*

Unexpected and unstable rapid crack growth among various damage developments is a serious problem for brittle materials. Therefore, it is useful to improve the reliability by adding the self-healing function to those materials, such as concrete, glass, and ceramics. Among them, self-healing ceramics, which can automatically repair micro cracks by using the oxidation reaction, are attracting attention. The mechanism of crack-repairing in ceramics imitates healing process of human bones. For example, alumina (Al_2O_3)/silicon carbide (SiC) particle composites is a typical self-healing ceramics [1]. In this material, when the crack occurs, SiC particles (self-healing agent) combined in Al_2O_3 matrix react with oxygen in atmosphere and change to silicon oxide (SiO_2). Then, the oxides fills up cracks by volume increasing. It has been clarified that the Al_2O_3/ SiC composite material is an excellent material system that can simultaneously achieve crack filling and high strength of the healing part [2]. However, for the evaluation of self-healing materials, unlike ordinary materials, novel numerical analysis methods to evaluate both the damage and healing processes as reciprocally continuous processes need to be developed. Under such circumstances, recent developments have been observed in formulating both damage and healing processes within the framework of the continuum damage mechanics [3].

In this study, we conducted the finite element analysis of Al_2O_3/SiC composite self-healing ceramics by using the damage-healing constitutive model based on the oxidation kinetics [3]. To verify the effectiveness of the constitutive model and analysis scheme, we used specimens with a chevron notch for the three-point bending test, which can suppress rapid fracture of cracks even in materials with low toughness. Then, we demonstrated the analysis results of repeated damage-healing processes within the framework of finite element method. It was confirmed that the present finite element analysis (FEA) methodology could reasonably reproduce the basic characteristics of strength recovery in self-healing ceramics. Thus, we concluded that the present FEA methodology can be used for studying the self-healing behavior linked with the microstructure distribution and fracture properties, which is essential for the mechanical and material design of self-healing ceramics.

Key Words: *low velocity impact, fibre reinforced polymer composite, micro-damage, intrinsic self-healing, micromechanical constitutive model, Abaqus/Explicit*

A micromechanics-based constitutive model for fibre reinforced polymer composites with intrinsic self-healing ability is presented in this work. Homogenisation is carried out using the Rule of Mixtures (ROM), i.e. equations defining mechanical properties of the homogenised composite. On the other hand, the Voigt (iso-strain) and Reuss (iso-stress) approximations are used as a means for localisation.

At the micro-scale, matrix constituent is modelled using the previously developed constitutive model comprising micro-damage-healing model and the isotropic hardening plasticity model described and validated in [1]. In this model, the effect of micro-damage on the matrix material is represented as deterioration of the elasticity modulus, whereas the healing phenomenon represents its recovery. Furthermore, the reinforcing fibres are modelled as transversely isotropic linear elastic material with Hashin fibre failure criterion and progressive fibre damage. The model was implemented in Abaqus/Standard user material subroutine UMAT and validated for static loading cases in [2].

The model is implemented into the Abaqus/Explicit user material subroutine VUMAT. Moreover, it is validated using low-velocity impact tests. Experimental results are taken from [3] where composite specimens consist of woven glass fibres as reinforcement and an epoxy-thermoplastic blend as the matrix constituent. The blend consists of diglycidyl ether bisphenol A (DGEBA) epoxy resin and poly($\boldsymbol{\varepsilon}$-caprolactone) thermoplastic polymer. Numerically, the warp and weft yarns are treated as unidirectional plies.

The model proves to be applicable for simulation of healing phenomenon after low-velocity impact damage in woven composite structures. Finally, the model could describe healing behaviour of other types of intrinsically self-healing composites if appropriate constitutive material laws are applied.

Key Words: *CFRPs, Self-healing, Melt Electro-writing, Diels-alder, Mode I, GNPs, Numerical simulation*

In the present work, a novel approach in terms of self-healing agent (SHA) incorporation into uni-directional carbon fiber reinforced plastics (CFRPs) has been demonstrated. More precisely, healable resin based on Diels-alder (DA) reaction mechanism, containing or not graphene nanoplatelets (GNPs) at the amount of 1% wt, was integrated locally into the mid-thickness area of CFRPs. The procedure was performed by the melt electro-writing process (MEP) technique. DA-based polymers present resin type behavior, while are mendable and present healing functionality through heating upon their melting point (T_m) temperature [**1**]. MEP is a processing technique for producing fibrous structures from polymer melts [**2**]. In this case of electrospinning technique, the collection of the fiber can be very focused. Therefore, combined with moving collectors, MEP is a way to perform 3D printing with ultrathin fibers. In our case, ultrathin fibers of DA resin were directly printed on the surface of CFRP pre-preg plies. Based on this, reference and modified CFRPs with (a) pure SHA and (b) SHA containing 1% wt GNPs were manufactured for the needs of the current study and further tested under Mode I loading conditions. Based on experimental results both types of modified CFRPs exhibited considerable enhancement of the fracture toughness properties with GNP modified ones to exhibit the best toughening performance (G_{IC} value was increased by almost 280%). After Mode I testing, the damaged samples passed through the healing procedure and then tested again under Mode I loading conditions. After repeating of the tests, acceptable healing efficiencies were achieved (up to 50%) as part of the fracture toughness properties were restored. GNP modified ones exhibited the best healing behaviour. Furthermore, numerical modelling and simulation of damage tolerance and healing capability of these CFRPs was performed via the development of appropriate cohesive zone models. The constitutive behavior of the cohesive zone was defined by the traction–separation relation derived from laboratory tests. The variation of the traction-separation relation after healing is directly related to the nature of SH material. This approach provides a robust numerical tool for the design of composite structures that include self-healing sites. Based on that, it was shown that simulated and measured R-curves are in good agreement. Finally, optical microscopy examinations not only showed that the epoxy matrix at the interface is partly infiltrated by the DA polymer, but it also revealed the presence of pulled out fibres at the fractured surfaces, indicating ductile behaviour due to SHA presence.

Lateral Resistance of Buried Pipes by Frictional Limit Analysis

Fabio C. Figueiredo[1*], Lavinia Borges[1], Luiz Felipe Moreira[1]

[1] UFRJ - Federal University of Rio de Janeiro, DEM, Av. Horácio de Macedo, 2030 – Ilha do Fundão – Centro de Tecnologia – bloco G-sl.201,Rio de Janeiro, RJ, Brazil, fabiofigueiredo@mecanica.ufrj.br

Key Words: Burried pipes, Limit Analysis, Friction, Porous materials

Pipelines are vital means of transportation of liquids and gases over large geographical areas. Regarding hydrocarbons, they must be flow at high pressure and temperature to avoid wax formation. Low temperatures may lead to deposits at pipe walls, increasing the pressure or blocking the fluid flux. Under such thermal and mechanical loads and Poisson's effect, the pipe tends to expand longitudinally. Since longitudinal movements are restricted, high compressible forces are developed, leading to buckling occurrence if a critical value is reached. The occurrence of lateral buckling strongly depends on the surrounding soil, friction at pipe-soil interface, pipe diameter and buried depth and subsoil characteristics [1]. Then, the evaluation of soil lateral resistance that will entail an imminent breakout is important.

This work aims the analysis of the soil lateral resistance under limit analysis formulation considering friction at pipe-soil interface. Limit analysis is a direct method, posed as an optimization problem with constraints, and aims the determination of the collapse power of an elastic perfectly-plastic body and do not consider the load history. In this approach, the pipe is considered as a rigid body while the soil mass is a deformable one. Then, at imminent plastic collapse state, the contact between the rigid and deformable bodies is assumed as known, with permanent contact at normal direction and a slipping rule at tangential direction. Coulomb friction law is considered. The limit analysis problem is solved by a quasi-Newton algorithm and a condensation technique allied to Lemke algorithm is used to solve the complementarity problem at contact. The cohesive soil mass follows the yield criterion proposed by [3], derived from homogenization theory considering cohesion, material internal friction and porosity.

The soil lateral resistance is evaluated by limit analysis considering friction at soil-pipe interface and porosity of soil mass, discretized by finite elements and under plane strain hypothesis. As results, the soil resistance forces per length, the velocity and stress fields at soil mass are determined as well as the slip lines.

Key Words: fracture, phase-field, dynamics, plasticity, shear bands

We propose a model to simulate dynamic ductile fracture based on a variational phase-field framework. In this framework, a coalescence dissipation term couples plasticity and fracture by degrading the fracture toughness as the equivalent plastic strain increases [1]. Compared to other models that degrade the plastic energy with damage, the current model avoids crack growth through plastic zones in compression and relaxes the upper bound on the regularization length. In addition, the variational framework allows for the consistent inclusion of plastic dissipation in the heat equation as well as thermal softening. Results from various benchmark problems in dynamic ductile fracture are presented to demonstrate the capabilities of the model. In particular, we demonstrate how the model is capable of capturing high strain rate effects such as brittle to ductile transitions and shear band formation. Importantly, these phenomena are naturally captured through the physics in the model, without the need for phenomenological criteria such as stability thresholds for the onset of shear band formation.

Numerical Simulation of Neck Propagation in Double Network Hydrogel

Isamu Riku* **and Koji Mimura**

Osaka Metropolitan University

Key Words: Neck Propagation, Hydrogel, FEM, Nonaffine Polymer Chains Network Model

Double network (DN) hydrogels have drawn much attention as an innovative material having both high water content and high mechanical strength and toughness. Futhermore, yielding phenomenon was observed in some tough DN gels[1]. For example, on tensile tests of DN gels that made from relatively sparse first networks, narrow zones appear in the sample and grow up with further stretching. During the neck propagation, a plateau region appears in the loading curve. The plateau value of the tensile stress hardly depends on the stretching rate. After the neck propagation, the gel becomes fairly soft, showing an elastic modulus *ca*. 1/10 of the virgin sample, and sustains large elongation, up to an elongation strain of around 20. The observations on the softened gels after the tensile test demonstrate that irreversible structural change takes place inside the gels, although their appearance is almost unchanged.

In this study, we at first employ a nonaffine polymer chains network model[2] to account for such irreversible structural change during the deformation of DN gels. And then, a finite element model of the DN gels under simple tension is constructed. On the other hand, neck propagation is one kind of localized instability and there will be a local transfer of strain energy from one part of the model to neighboring parts. This class of problems has to be solved either dynamically or with the aid of (artificial) damping; for example, by using dashpots. Fortunatly, Abaqus/Standard provides an automatic mechanism for stabilizing unstable quasi-static problems through the automatic addition of volume-proportional damping to the constructed model and the applied damping factors can vary spatially and with time to account for changes over the course of a step, where the damping factor is controlled by the convergence history and the ratio of the energy dissipated by viscous damping to the total strain energy. Furthermore, Abaqus/Standard can reduce the time increment to permit the process to occur without the unstable response causing very large displacements.

The simulation results show that the nonaffine polymer chains network model can be employed to reproduce neck propagation in DN gels very well.

Applicability of Modified von-Mises Damage Criterion to Compressive Fracture Behaviour of Cement-Based Materials

Hiroto Masui [1*] and Mao Kurumatani [2]

[1] Ibaraki University, 4-12-1, Nakanarusawa, Hitachi, Ibaraki 316-8511, Japan, 21nm836a@vc.ibaraki.ac.jp
[2] Ibaraki University, 4-12-1, Nakanarusawa, Hitachi, Ibaraki 316-8511, Japan, mao.kurumatani.jp@vc.ibaraki.ac.jp

Key Words: *Modified von-Mises criterion, Damage Model, Compressive Fracture, Crack Growth, Cement-Based Materials*

The Applicability of the damage model based on the modified von-Mises criterion [1] is studied for compressive fracture behaviour of cement-based materials such as mortar and concrete. Two numerical experiments of mortar plates with a circular hole under compression are presented, and the results are compared with experimental results to demonstrate the applicability of the modified von-Mises criterion for compressive fracture behaviour.

We first show the formulation of the damage model based on fracture mechanics of concrete [2]. The damage model evaluates the generation and propagation of cracks by using the modified von-Mises criterion. Cohesive crack growth in cement-based materials can be represented by introducing the traction-separation law based on the fracture energy into the damage model. The fracture simulation of cement-based materials involving cohesive crack growth is performed in the non-linear finite element framework.

The crack propagation behaviour simulated with the modified von-Mises damage model is compared to existing experimental results. The comparison shows that the numerical results are in good agreement with the experimental results. This implies that the damage model with the modified von-Mises criterion allows the simulation of cohesive crack growth in cement-based materials subjected to compressive load. To verify the capability for simulating the compressive fracture behaviour quantitatively, the numerical results are also compared to our own test results with the DIC measurement. From these results we confirm that the damage model with the modified von-Mises criterion is applicable to the crack propagation analysis of cement-based materials subject to compressive load.

Key Words: *RBSM, Cracking, Collapse simulation, Geometric nonlinearity, Contact problem*

In order to accurately reproduce the collapse behavior of concrete structures, an algorithm to update the network between elements is introduced in the Rigid-Body-Spring Model(RBSM) considering geometric nonlinearity [1][2]. Specifically, a new network was constructed by placing multiple contact-determining spheres on Voronoi polyhedral elements and a reduced integration Timoshenko beam element between the newly-determined contact elements. As a result, in the numerical simulation of concrete structures, a contact phenomenon after large displacement and large rotation behavior, which could not be reproduced by the conventional RBSM, can be reproduced.

Key Words: *Ductile fracture, Computational mechanics, Crack initiation, Crack propagation, Gurson, Cohesive zone model*

For the computational simulation of ductile fracture associated with void growth and coalescence, various computational methods have been developed [1]. However, most computational methods such as continuum damage models suffer from mesh dependent issues, and thus a regularization term and/or a length scale parameter is introduced to alleviate the mesh dependency. In this study, the Gurson model and cohesive zone model are integrated to reproduce ductile fracture behaviors [2]. The transition from the plastic deformation to the cohesive fracture is linked using the porosity-based crack initiation criterion in conjunction with the stress triaxiality. The Gurson-Cohesive model (GCM) is validated using experiments performed by Sandia National Laboratory [3]. Both tensile coupon tests and compact tension tests are investigated with the same material properties within the unified computational framework. The computational results reproduce the engineering stress-strain curve and the area reduction ratio for the tensile coupon test. The proposed framework captures the load versus crack opening displacement relations for the compact tension tests with three cases of the initial notch length. Furthermore, the computational results converge under mesh refinement without introducing any regularization term and/or length scale.

Key Words: *fractures, discrete element methods, strain energy field, sintered materials.*

Discrete Element Methods (DEM) are good alternatives to FEM for the study of fractures in brittle solid materials [1]. However, their precision is limited by the size of the elements used to represent the material. Hereby we study fractures in brittle materials by using smaller discrete elements just on the places where stresses are closer to the breaking thresholds. The solid material is divided into three-dimensional random Voronoï cells, and each cell, each of them a discrete element, is represented by a frozen clump of overlapping spheres [2]. If two cells share a face, the spheres of one cell in contact with those of the neighbouring one are joined across the face with rigid bars [3]. The forces and torques of such bars are used to compute the strain energy field, who has shown to be adequate to account for fractures in granular media [1]. Once the material is charged with an external load, only discrete elements with high strain energy fields are subdivided into smaller elements, who re-establish bonds between them and with all neighbours. The process is repeated until the desired resolution is reached, and then those bonds above a threshold are broken. In this presentation we show how the fracture surface can be retrieved with high accuracy and low computational costs, and the results are compared to continuum methods like FEM.

In the present investigation, the crack propagation phenomena of 1TCT specimen made of stainless steel (SUS316) under large magnitudes of monotonic and cyclic loads are presented. The specimens experienced large deformations. In order to characterize the crack propagation, the J-integral [1] and the J-integral range ΔJ [2] have been adopted. It is, however, noted that the applications of the J-integral and the ΔJ were limited in infinitesimally small deformation problems. For example, Okada et al. [3] performed two-dimensional analyses under the assumption of infinitesimally small deformation. The fracture parameter T_ε^* -integral was proposed. It was defined as an integral on an infinitesimally small contour Γ_ε surrounding the crack tip. T_ε^* measures the deformation energy dissipating into the small region (process zone) V_ε surrounded by Γ_ε per unit crack extension. For the numerical computation, the T_ε^*-integral is written as a combination of far field contour and area integrals. Arai et al. [4] redefined the three-dimensional J-integral using the domain integral representation as an extension of the T_ε^*-integral to three-dimensional and finite strain elastic-plastic problems. It measures the energy dissipating into a small volume V_ε^o per unit crack extension. Then, the ΔJ was proposed by its extension to cyclic load problem (Arai et al. [5]).

In the presentation, the applications of the newly redefined three-dimensional J-integral and ΔJ to the fracture problems involving finite strain elastic-plastic deformation and cyclic load will be discussed. The experimental data of the JWES database [6] was used as references for the finite element analyses.

Key Words: *Welding, Residual stress, Electron beam welding, Stainless steel*

The high residual stress on the surface of the canister has a great influence on the occurrence of Chloride-Induced Stress Corrosion Cracking (CISCC). In conventional welding for stainless steel Post-Weld Heat Treatment (PWHT) cannot be performed, resulting in high residual stress. Since electron beam welding is known to have a smaller Heat Affected Zone (HAZ) width compared to conventional welding, applying electron beam welding to canister is expected to reduce residual stress and reduce the occurrence of CISCC.

Purpose of this study is to compare the residual stress distribution of a mock-up canister (Sandia National Laboratories Mockup canister) manufactured by conventional welding (Submerged Arc Welding, SAW) with the residual stress distribution when the conventional welding is replaced with electron beam welding. Electron beam welding was applied to the canister through finite element analysis using ABAQUS. The component was made from 304L stainless steel (SS). The analysis was carried out using uncoupled thermal and mechanical finite element analysis. Three-dimensional (3D) finite element models were used to simulate thermal and mechanical analysis. Thermal analysis was performed by simulating a moving cylindrical heat source. Stress analysis was performed using the results of thermal analysis and residual stress was calculated. The residual stress calculated through this analysis was compared with the residual stress measured by Sandia National Laboratories for a canister manufactured by conventional welding (SAW).

Key Words: *High Strength Steel, Ductile Fracture Criterion, Stress triaxiality, Lode parameter*

The use of high-strength steel in automobile manufacturing processes is increasing to reduce the durability and weight of automobile bodies and chassis. High-strength steel has higher strength than conventional materials, but has less ductility. Therefore, it is very sensitive to cracks occurring in cold processing processes, such as microcracks, which may cause damage or defects, especially in trimming or shear or punching processes. Defects caused by microcracks such as edge cracks are a very serious problem in product quality and productivity. Therefore, predicting the fracture of thin plate is a very important problem.

In predicting the ductile fracture of metals, many ductile fracture criteria have been proposed. McClintock, Rice, and Tracey argued that stress triaxiality is an important factor influencing the nucleation, growth and coalescence of microscopic voids and the ductile fracture criterion was presented as a function of stress triaxiality [1,2]. Xue and Wierzbicki confirmed through various experimental results that the Lode Angle parameter had a mutual effect on the initiation of ductile fracture like stress triaxiality [3, 4]. Bai and Wierzbicki modified the Mohr-Coulomb (MMC) criterion to predict many different types of specimen fracture under various stress triaxiality and lode angle parameter [5].

Previous ductile fracture criterion such as MMC model have many parameters and it is hard to decide the parameters. In this study, previous ductile fracture criterion using stress triaxiality and lode parameter was simplified. The constant of the simplified model was determined using tensile test specimen and SENT specimens which have two different notch radii for JSC 590 and JSC 980 materials. In addition, the validity of the proposed model was verified by applying the simplified model to the DENT specimens.

Crack Propagation Criterion for a Pipe under Bending and Torsion Loadings

Kiyokazu Tsuhara[1*] and Yoshitaka Wada[2]

[1] Kindai University, Higashi-Osaka, Osaka, Japan, Kiyokazu.Tsuhara353@kindai.ac.jp
[2] Kindai University, Higashi-Osaka, Osaka, Japan, wada@mech.kindai.ac.jp

Key Words: *Finite element analysis, Bending, torsion, Multiple loads, Stress triaxiality, Equivalent plastic strain*

In the previous study[1][2], ductile crack propagation behavior was reproduced by results of Central Research Institute of Electric Power Industry (CRIEPI) [3] under monotonic and cyclic loading bending tests for pipes installed in a light water reactor plant. It is also concluded that the crack propagation conditional equation with parameters of stress triaxiality and equivalent plastic strain proposed by Kumamoto[1] and Ohbayashi[2] can be reproduced.

As mentioned above, the analyses are reproduced from four-point bending tests under monotonic and cyclic conditions. On the other hand, experiment results subjected to multi-axial loads including bending and torsion are very few examples in order to ensure the validation of proposed criteria.

Recently, the CRIEPI conducted an experiment under combined bending and torsion on stainless pipe. The results are evaluated using numeriacl simulations by several organaizations and are checked in a round-robin analysis to ensure the validity of the results.

In this study, FE models are generated on 20 mm diameter stainless steel pipes with through-wall crack under combined bending and torsion and are simulated including ductile crack propagation. In addition, Otsuka et al.[4] have suggested that an increase in stress triaxiality accelerates the extension rate of voids and decreases plastic strain of ductile fracture. Therefore, it is reasonable to propose an equation using these parameters. Crack propagation criterion will be proposed using those results and are evaluated the validity of the criterion.

In this study, a system referred to as *sim2d* for fatigue crack propagation analysis based on extended finite element method (XFEM), which can model crack independently of finite elements, has been developed. This system employes an in-house XFEM code referred to as *NLXFEM3Dstruct* [1] and python scripts to control the code execution. A fatigue crack propagation analysis of a carbon steel compact tension specimen has been performed by the developed system as a verification. In this presentation, the analysis results by *sim2d* including the relationship between the crack length and the number of load cycles are compared with the results obtained by conventional finite element method (FEM), which requires re-meshing on each analysis step for crack propagation, and the reference solution in accordance with ASTM standard [3].

Dynamic failure simulation of metal materials and structures under blast and impact loading

Zhanli Liu*, Yigang Wang and Dongyang Chu

Department of Engineering Mechanics, School of Aerospace Engineering, Tsinghua University, Beijing 100084, P.R.China

Key Words: *Dynamic failure, Fracture, Shear band, Numerical simulation*

Studying the dynamic failure laws of metal materials and structures under blast and impact loading by numerical simulation is of great significance for characterizing the damage effects of explosive shock and designing novel impact-resistant structures. The metals' failure under strong dynamic loading involves multiple complex physical processes, such as the large deformation, the thermal-mechanical coupling, and the material state changes. These complex physical processes bring great challenges to numerical simulation, including the geometric description of complex dynamic failure modes such as cracks and shear bands, the determination of failure criteria, and the description of plasticity-damage coupled evolution, etc. In response to these challenging issues, a theoretical and computational thermal elastic-plastic phase field model is established based on the energy variational principle to describe metals' dynamic failure. The model realizes a unified description of the crack and shear band, and its efficient explicit finite element solved strategy is proposed. The model is further applied to three typical metals' dynamic failure issues under blast and impact loading: the transition of brittle and ductile failure modes of metals, the self-organization of adiabatic shear bands (ASBs), and the transition of failure modes of thin-walled disks under shock waves. This verifies the accuracy of the theoretical model and the robustness of the computational model. This work lays the foundation for the subsequent development of damage assessment and protective structure design for blast and impact loading based on simulation.

Key Words: *Isogeometric Analysis (IGA); Fracture mechanics; Three-dimensional; Stress singularity; Stress Intensity Factor (SIF)*

A study on J-integral computation for three-dimensional Isogeometric Analysis (IGA) has been conducted. IGA is a novel analysis method that has been investigated by researchers and engineers in the last decade. IGA was initially developed and presented by Hughes et al. [1]. One of the possible applications of IGA is fracture mechanics. In fracture mechanics, accurate evaluations of Stress Intensity Factors (SIFs) are very important. In the applications of the Finite Element Method (FEM), two-dimensional J-integral by Rice [2] has often been used to evaluate the SIFs. The extension to three-dimensional was carried out by Blackburn[3] and Kikuchi et al. [4]. The domain integral method for three-dimensional J-integral was presented by Li et al. [5]. In this study, a domain integral method suited for IGA is presented. In the present IGA, the second order B-spline and Non-Uniform Rational B-Splines (NURBS) functions are adopted as basis functions. A singular patch method to express the singular stress field in the vicinity of the crack front following the idea of Barsoum's quarter-point finite element [6]. Examples of embedded and surface elliptical cracks to demonstrate the accuracy of the proposed J-integral are presented.

Proposal of Crack Propagation Criterion Considered Constraint Effect under Extremely Low Cycle Fatigue; Evaluation by 1.5T-CT Specimen

Kazuma Kida[1*] and Yoshitaka Wada[2]

[1] Kindai University, Higashi-Osaka, Osaka, Japan, kida.mech@kindai.ac.jp

Key Words: *Extremely low cycle fatigue, Fracture criterion, Constraint effect, Finite element analysis, Stress triaxiality, Equivalent plastic strain increment*

The prediction of fracture behavior under extremely low cycle fatigue due to excessive loading is necessary for the life assessment of structures. ΔJ criterion has been used to assess the life under low cycle fatigue. However, the applicability of this method is not well confirmed under extremely low cycle fatigue. Fracture toughness is dependent on the loading conditions and geometry due to the constraint effect.

In the previous study [2], a crack propagation criterion was proposed for a 1T-CT specimen of SUS316, focusing on the physical quantities near the crack tip. These are the stress triaxiality and the equivalent plastic strain increment. The former is a parameter related to the growth of voids in ductile fracture, while the latter is a parameter that indicates the degree of plastic deformation. However, no comparison has been performed for specimens of different shapes or materials, and more detailed verification is required.

The objective of this study is to evaluate the validity of the crack propagation criterion proposed in the previous study [2] by applying it to CT specimens of different thicknesses and materials.

In this study, two types of crack propagation simulations were performed on a 1.5T-CT specimen of SGV410 under extremely low cycle fatigue fracture tests using the finite element code, ANSYS. The first one is generation phase simulation. In the simulation, the physical quantities near the crack tip were obtained and the parameters of the crack propagation criterion were identified. The second one is the validation phase simulation, in which the crack propagation criterion is used as the crack propagation criterioin to evaluate whether the experimental crack propagation behavior can be reproduced.

The results of both the generation phase simulation and the validation phase simulation are in good agreement with the experimental results.

We'd like to disscuss the accuracy of prediction by the proposed crack propagation criterion under extremely low cycle fatigue.

Proposal of Crack Propagation Criterion Considered Constraint Effect under Extremely Low Cycle Fatigue; Evaluation by 1T-CT and 2T-CT Specimen

Yuto Kishi[1*] and Yoshitaka Wada[2]

[1] Kindai University, Higashi-Osaka, Osaka, Japan, kishi.yuto0714@kindai.ac.jp
[2] Kindai University, Higashi-Osaka, Osaka, Japan, wada@mech.kindai.ac.jp

Key Words: *Extremely low cycle fatigue, Finite element analysis, Constraint effect, Fracture criterion, Stress triaxiality, Equivalent plastic strain increment*

It is important to understand unstable fatigue fracture mechanism because fracture accident is occupied fatigue 80% of the total [1]. However, a highly reliable evaluation method for under extremely low cycle fatigue caused by earthquakes has not yet been developed because of variable fracture toughness due to the constraint effect with large deformation.

Crack propagation criterion proposed in the previous study was validated under restricted condition [2], however it wasn't considered constraint effect. The objective of this study is the proposal of crack propagation criterion considered constraint effect under extremely low cycle fatigue.

As a matter of procedure, we model compact tension specimen finite element it was used in the previous study changed the thickness which is one of the constraint effect. And then after analysis which simulates behavior based on the experiment, we conducted validation applied crack propagation criterion which was proposed in previous study.

As a result, analysis applied crack propagation criterion in the previous study was obtained good accuracy. Crack shape was formed following distribution of effective plastic strain in thickness dimension. As a reason for that contribution ratio of effective plastic strain in crack propagation criterion is higher than stress triaxiality. In the presentation, crack shape in the analysis will be discussed after re-examination the contribution ratio in physical quantities and the method of evaluation.

The crack propagation criterion in the previous study is confirmed validity in several cases of thickness. We'd like to discuss validity in cases of different material properties, specimen shapes and crack shape.

Key Words: *Non-destructive Evaluation, Polymer-Matrix Composites, Delamination, Topology Optimization, Ultrasonic Wave Propagation*

This study proposes a new method to identify delamination shape in carbon-fiber-reinforced plastic (CFRP) laminates using topology optimization and visualization of ultrasonic waves. Although the technique to visualize ultrasonic wave propagation aids in detecting defects such as delamination, it is difficult to evaluate them quantitatively. The authors [1] proposed the topology optimization-based damage identification method combined with the technique and quantitatively identified the crack in a metal plate. Application of the proposed method to predicting critical damage in composite structures, such as delamination, will enhance structural reliability.

The concept of the proposed method is to estimate the defects as the distribution of 'damage parameters' that reproduces the experimentally visualized ultrasonic wave propagation on an inverse analysis model. In this study, delamination is modeled using cohesive elements [2] and is estimated as distribution of the internal residual strength variables that minimizes the error between the ultrasonic features obtained in the experiment and those in the finite element analysis.

To verify the feasibility of the present method, this study applied it to a cross-ply CFRP laminate with an artificial delamination. The stacking sequence of the specimen was $[0_4/90_4]_S$ and the artificial delamination was introduced by a 10×10 mm polyimide film at one of the two interfaces of the 0° and 90° layers. When the delamination identical to the specimen was developed by the cohesive elements and when the finite element analysis was performed under the same condition as the experiment, the maximum amplitude of the analysis was high within the delamination area, which was the same result as the experiment. Therefore, the optimal distribution of the internal residual strength variables can be estimated by minimizing the error between the maximum amplitude map acquired in the experiment and in the inverse analysis model.

Under the above-mentioned procedure, the shape of the artificial delamination was successfully estimated using the present method. The detailed results and discussion will be demonstrated in the presentation.

Key Words: Shear lag modeling, Computational homogenization

In this presentation we revisit the well-known, one-dimensional shear lag model introduced by Kelly and Street [1]. Owing to it's simplicity, it is widely used in material sciences to assess and interpret experimental results. Originally the model was proposed to evaluate the stationary creep response of circular fiber reinforced materials with large fiber aspect ratios and low fiber volume fractions. Other applications include square fibers and cellular materials [2].
However, it is usually difficult to evaluate experimentally whether the model is appropriate for the given material, as morphology modification is limited due to strongly interrelating solidification and processing parameters and as test conditions are limited to uniaxial creep tests.
The goal of the present study is to use modern FFT-based solvers [3, 4] to evaluate the suitability of the Kelly-Street model for various materials with changing morphology (volume fractions and aspect ratios). Therefore we use artificially generated microstructures, which offer the flexibility of adjusting morphology. We evaluate stationary creep response and compare simulated results against Kelly-Street model predictions.
As will be shown, for certain fiber aspect ratios and volume fractions the Kelly-Street model fails to predict stationary creep accurately, which is linked to basic model assumptions. This observations motivates subtle, physically motivated modifications of the model. We will show, that the accuracy of Kelly-Street model predictions can be significantly improved, which allows future usage to obtain accurate estimates of creep behavior for various morphological features.

Key Words: *CFRP laminate, FEM, Damage propagation, Zig-zag CZM, Impact test, CAI test*

Due to high specific strength and stiffness, carbon fiber reinforced plastics (CFRP) have been widely used in aviation industries in recent years. However, CFRP laminate is susceptible to out-of-plane load, which can lead to complex damage such as delamination, matrix crack and fiber breakage. Because the damage may cause a decrease in compressive strength, CAI (Compression After Impact) strength is important in designing CFRP laminate structures.
In this study, Finite Element Method (FEM) is used for strength evaluation of structures. Interface elements considering Cohesive Zone Model (CZM) are introduced to model multiple delamination and matrix cracks of laminate. For nonlinear problem, such as evaluating damage propagation behavior of structures under large deformation, it is generally necessary to use explicit dynamic finite element analysis using mass scaling. However, in order to perform efficient analysis, it is worth studying implicit analysis using cohesive zone model considering Zig-zag softening law to improve convergence [1].
In this presentation, the implicit method is used to perform damage propagation analyses of CFRP laminates subjected to out-of-plane load, and subsequently subjected to compressive load. The results including size of damage in the impact test analysis and CAI strength in the CAI test analysis are compared with those of experiments performed by JAXA [2] and discussed.

Damage Simulation for Textile Composites Using Fiber-bundles / Matrix-resin Separated Mesh

Akinori Yoshimura[1*], Takanori Sugiura[1], Keita Goto[1] and Masahiro Arai[1]

[1] Nagoya University, Furo-cho, Chikusa-ward, Nagoya, Aichi 464-0083, JAPAN,
akinori.yoshimura@mae.nagoya-u.ac.jp

Key Words: Finite element analysis, Damage analysis, Cohesive zone model, CFRP, Woven composites

In this study, the authors propose a novel progressive damage simulation method for textile composites. The method is based on finite element analysis in which fiber bundles and matrix resin are separately meshed. Two meshes are connected using cohesive zone model (CZM), which is also utilized to simulated interface damage between fiber bundle and matrix resin. Damage in the fiber bundle and matrix resin are simulated using continuum damage mechanics (CDM) model.

In the conventional finite element analysis of textile composites, the mesh must be divided along the interface between fiber bundles and matrix resin. The meshing process is often difficult and labor consuming because of the complex shape of textile microscopic structure. Moreover, textile structure often results in small, distorted resin elements surrounded by the fiber bundles. Such elements increase the calculation cost and reduce the calculation accuracy. In the proposed method, however, fiber bundles and matrix resin are separately meshed. Moreover, regular cubic grid mesh can be used for modeling matrix resin. It means that small, distorted resin elements are no longer necessary, and element division process becomes much easier.

In the presentation, formulation of the proposed method will be presented first. Progressive damage simulation analysis for simple textile composites will then be performed using the proposed method, and the results will be compared with those of conventional damage simulation for validation of the method. Calculation costs will be compared for demonstrating the effectiveness of the proposed method. Finally, progressive damage simulation for 3-dimensional woven composites, which have complex textile microscopic structure, will be presented for demonstrating the effectiveness of the proposed model.

Development of a Novel Element for Simulating CFRP Strength Deterioration due to Cyclic Loadings Based on Entropy Damage

Jun Koyanagi[1*], Asa Mochizuki[1], Ryo Higuchi[2], Vincent Tan[3] and Tong Earn Tay[3]

[1] Tokyo University of Science, 6-3-1 Niijuku, Katsushika-ku, Tokyo Japan,
koyanagi@rs.tus.ac.jp (https://www.rs.tus.ac.jp/koyanagi/home.html)

[3] National University of Singapore, 21 Lower Kent Ridge Road Singapore 119077,
mpetanbc@nus.edu.sg

Key Words: *FEA, Strength deterioration, Cyclic loading, Hashin criteria, Entropy damage*

We developed a novel element for finite element analysis to simulate strength degradation of CFRP under cyclic loadings. The failure criterion is based on Hashin criteria [1]. The six types of strengths in Hashin criteria: fiber directional tensile, fiber directional compressive, transverse tensile and transverse compressive, fiber axial shear, and transverse shear strengths, are degraded respectively, depending on corresponding cyclic loadings. It is to say, damage initiation criteria change with respective cyclic loadings. The issue attributes to how the strength degrade in response to the cyclic loadings.

CFRP consists of elastic fiber and viscoelastic matrix so CFRP possesses viscoelastic characteristics more or less. The dissipated energy due to viscoelastic behavior is divided by absolute temperature, which becomes entropy increase. The entropy increase directly relates to the damage of material [2]. Sato et al [2] predicts residual strength of CFRP after some loadings, utilizing entropy damage criterion which is calculated based on viscoelastic constitutive equation of polymer resin. This criterion is applied in this study.

The orthotropic viscoelastic constitutive equation is assumed in this study. The viscoelastic model is expressed by general spring and dashpot systems. Depending on loading history including cyclic loadings, both springs and dashpots move. The work for movement of dashpot corresponds to dissipated energy so entropy increase can be identified always. The strengths in Hashin criteria are degraded according to the entropy increase. The entropy increase consists of amount of each directional dissipated energy divided by absolute temperature.

In respect to damage evolution, the energy release rate is also degraded according to the dissipated energy, even after damage initiation. Therefore, during damage evolution traction separation behavior becomes nonlinear. ABAQUS user subroutine is employed in this study. Thus, we have developed a novel element which can simulate deterioration caused by essentially various loadings.

The element can simulate not only strength degradation caused by monotonic cyclic loading, but also various cases such as stress level, frequency, stress ratio, even temperature changes. Hence, the element can be inherently used universally for long-term durability of CFRP. Some application examples are shown in this presentation.

Key Words: *Multiscale, Multiphysics, Transient analysis, Structural finite elements*

FE^2 offers an attractive approach to finite element analysis (FEA) of composites because it is often difficult to obtain accurate homogenized constitutive relations due to complex microstructures and the nonlinear interactions among the constituents of the composites. Homogenized properties are obtained through FEA of representative volume elements (RVE) where the different phases of the composite are explicitly modelled. However, the conventional implementation of FE^2 requires familiarity with computational homogenization and some in-house coding. The RVE calculations need to be carried out in tandem with the FEA of the composite structure with constant information exchange between the micro and macro scale simulations. We recently proposed a much simpler implementation - Direct FE^2 - that enables FE^2 to be carried out on commercial FE codes with only two pre-processing steps [1]. This was demonstrated in an example of the deformation of a 2D composite beam cantilever beam with geometric and material nonlinearities using solid finite elements.

The implementation of Direct FE^2 for composite materials for other types of analyses will be presented. Leveraging on the capabilities of ABAQUS in thermal and transient analyses, we show how coupled multiscale thermomechanical problems can be solved [2] and how inertial effects can be incorporated at the microscale [3]. Direct FE^2 for beam and plate elements, which are important FEA of composite laminates because of their computational efficiency, is also presented.

Key Words: *Morphing Wings, Control, Flight Dynamics, Aeroelasticity*

Conventional aircraft wings have rigid control surfaces to control the aircraft flight, but those devices induce abrupt shape changes of the wing and gaps on the surface. Morphing technology, which enables smooth wing shaping, can improve the aerodynamic characteristics of the aircraft, and it has been extensively studied for the last decades.

A flexible structure that makes the smooth wing shape change possible is one of the key components of morphing technology. One of the promising structures is a corrugated structure. The morphing concept with corrugated panels has been investigated, which demonstrated that the corrugated morphing wing can improve the static aerodynamic performance and that it is a feasible morphing concept with a simple actuation system [1,2].

The aforementioned studies demonstrated the static aeroelastic characteristics of corrugated morphing wings, but the performance of the morphing aircraft remains to be investigated. Corrugated structures are very flexible, and the flexibility may affect the flight performance of the entire aircraft [3]. Detailed studies are needed to understand the flight characteristics with corrugated morphing control surfaces.

The objective of this study is to understand the influence of the flexible corrugated morphing structures on the flight dynamics of the entire aircraft. An aeroservoelastic simulation framework for corrugated morphing control surfaces has been developed combining a finite element method, an unsteady vortex lattice method, and a linear quadratic regulator. By coupling the rigid-body flight dynamic formulations with this framework, the flight motions of the morphing aircraft will be numerically simulated. The interactions between the rigid-body flight dynamics of the entire aircraft and the flexible corrugated morphing structures will be demonstrated in representative flight conditions.

Key Words: *Multi-scale, Micro-inertia, Dynamics, Heat transfer, Micromorphic*

FE2 is an appealing approach for efficient modelling heterogeneous materials with constituent properties compared with direct numerical simulation. But FE analyses at the macroscale and the microscale have to be performed in a nested manner. Direct FE2 recently proposed by Tan et al. [1] overcomes this deficiency through formulating a single FE analysis, in which both macro and micro DOFs are involved and coupled through kinematical constraints. Therefore, it can be directly implemented in existing FE software and largely simplifies the modeling. An underlying assumption of the classical FE2 or Direct FE2 is the separation of length scales, namely, the microscopic length is much smaller than the macroscopic characteristic length. However, this assumption may not always hold in advanced materials or structures, such as metamaterials and micro-devices.

In this presentation, novel formulations of Direct FE2 are proposed for heterogeneous problems in two situations where the scale separation is not fully satisfied. The first one is a static analysis. Instead of the classical Cauchy continuum, a micromorphic continuum is employed at the macroscale [2]. Besides the first-order displacement gradient, nonlocal kinematic fields are introduced and therefore a higher-order deformation mode at the microscale is modelled. The second one is a transient analysis. While a stationary micro-scale problem is normally assumed in the classical method, micro-inertia is considered herein [3, 4] and its importance is highlighted, especially the inertia contributed by the inclusions. It is shown that the implementation with Direct FE2 remains simple albeit the complicated microscopic responses. Finally, the proposed formulations are verified through several numerical examples, in which interesting physics phenomena are captured including size effects and wave mitigation.

Key Words: *CFRP, Cyclic Loading, Numerical Analysis*

In order to evaluate the durability of CFRP, it is necessary to understand the damage and fracture behavior of the resin part. In order to evaluate the durability of CFRP, it is necessary to understand the damage and fracture behavior of the resin part. Conventional studies on the damage and fracture behavior of base resin have been limited to discussions under specific conditions[1,2]. However, in order to essentially discuss durability, it is necessary to establish a constitutive law for the resin that can evaluate the residual strength after experiencing various loading histories. With regard to the damage criterion, recent attempts have been made to clarify the damage evolution of materials based on irreversible thermodynamics. It is known that the thermodynamic entropy increases with the deformation of a material and fracture occurs when it reaches a certain value[3]. Therefore, it is expected that the irreversible entropy in materials can be a criterion to evaluate the damage of materials. In recent years, CFRP is required to have a design life of several decades depending on the field, and fatigue strength as well as static strength is becoming more important to ensure safety.. The purpose of this study is to predict the effect of fatigue on the base resin PA6 of CFRP as the first step of the long-term fatigue analysis of CFRP considering the nonlinear viscoelastic-viscoplastic constitutive law with entropy damage and the temperature and time dependence of the base resin. In this study, we first coded a viscoelastic-viscoplastic model that considers the damage caused by energy dissipation. Here, the damage is calculated from the energy dissipation due to the deformation of the dashpot, and when the damage reaches 25% (i.e., 25% voids), the elastic modulus is reduced to the original 1% because the resin becomes almost non-functional, and the stress of the previous increment is also calculated sequentially according to the updated elastic modulus. Then, uniaxial cyclic loading simulations were performed on a simplified model of discontinuous fiber CFRP, which was adapted from the viscoelastic-viscoplastic model presented earlier. The proposed viscoelastic-viscoplastic model was applied to a simplified model of discontinuous fiber CFRP, and uniaxial cyclic loading simulations were performed with a strain amplitude of 3.0×10-2, 30 cycles of tension and compression, and a strain frequency of 0.2 Hz. As a result, stress relaxation due to viscoelasticity was observed up to about 60 seconds, and after that, stress decreased as the number of damaged and destroyed resin elements increased. In this study, the proposed viscoelastic-viscoplastic model was applied to a simple model of discontinuous fiber CFRP, and uniaxial cyclic loading simulation was performed. As a result, stress relaxation due to viscoelasticity and stress reduction due to damage fracture of the resin were shown. The results showed that the stress relaxation by viscoelasticity and the stress reduction by resin damage and fracture were observed. For the long-term fatigue analysis of CFRP, it is necessary to simulate the cyclic loading with a model closer to the reality, and to compare the results with the experimental data and fitting.

Key Words: *FEA, Viscoelasticity, Thermodynamic Entropy, Damage Mechanics, Failure Prediction*

The long-term durability of viscoelastic materials is very important for discussing the durability of polymer composite materials. The polymer materials used for matrix of composite have time and temperature dependent characteristic which called viscoelasticity. In order to describe the material behavior accurately, a time- and temperature- dependent constitutive equation considering material damage is required. In this study, we propose a viscoelastic constitutive equation for viscoelastic media based on irreversible thermodynamics and viscoelastic theory [1] in order to predict failure behavior of heat-resistant carbon fiber reinforced plastics (CFRP). Regarding the material damage law, we introduce a thermodynamic entropy to material damage. It has been attempted to clarify the damage evolution in solid materials from irreversible thermodynamics in recent years [2]. Inelastic deformation of the material causes an irreversible structural change inside the material. Such an internal structural change is expressed by a thermodynamic internal variable based on Clausius-Duhem inequality (the second law of thermodynamics); i.e., deterioration of the material proceeds with the disorder of the system. The disorder in the system, which causes deterioration of the characteristics, is raised by the mechanical deformation and the entropy increases accordingly. The disorder in the degraded system continues to increase to the critical state and causes the failure of the materials. Therefore, irreversible entropy in materials can be used as a criterion for evaluating durability of materials. Single axis tensile tests are performed under various temperature and strain rates to determine the material properties and the amount of entropy generation. Furthermore, we introduced presented constitutive equation into representative volume element (RVE) model in order to predict the initial cracking under fatigue condition. Fatigue tests for cross-ply laminates are conducted to verify presented model.

CFRP sandwich composites are finding increased use in various industries including aerospace and automotives due to many distinct advantages. However, they are highly susceptible to debonding and delamination damages especially under fatigue loadings or unexpected impacts during the manufacturing and in-service process. These damages could reduce the mechanical performance of the composite and thus pose serious problems for the safety and integrity of the whole structure. Guided wave (GW)-based inspection techniques are one of the potential solutions to detect such hidden defects in composite structures because GWs are able to propagate over a long distance and penetrate into internal laminates. Conventional GW-based inspection uses either immersion or contact transducers. This is frequently not practical, particularly under harsh environments or with large structures for field inspection. A non-contact inspection technique for delamination and disbond in a sandwich structure is demonstrated in this work using air-coupled ultrasonic guided waves. The sandwich plate used in this study comprises of a Nomex® honeycomb core embedded between two CFRP composite skins. The dispersion characteristics of the CFRP laminate and sandwich plate are investigated both in numerical simulation and experiment to validate the constructed numerical model of the sandwich structure. The inspection frequency, wave mode as well as incident angle of the air-coupled transducer can be determined by frequency-wavenumber analysis. Numerical simulations are further conducted to explore guided wave propagation mechanics due to delamination and disbond. Both the delamination and disbond can be detected in numerical simulation. A parametric study is carried out to optimize the configuration of air-coupled transducers in simulation. The set-up of transducers is subsequently applied in the experiment for the disbond identification. Tests have been carried out on honeycomb sandwich samples with disbond. The measurements are compared with numerical predictions and good agreement is obtained.

Improved Numerical Simulation of Woven Textile Membranes using Stress-Ratio-Dependent Material Properties

Mehran Motevalli[1*] **and Daniel Balzani**[2]

[1,2] Ruhr University Bochum, Universitaetstr. 150, 44801 Bochum, Germany

Key Words: Woven Textile Membranes, Nonlinear Material Modeling, Improved Structural Simulation

A newly proposed hyperelastic orthotropic material model [1] for the geometrically nonlinear simulation of woven tensile membranes is extended to become the basis of a new approach for structural simulations of higher accuracy. The model is polyconvex and benefits from anisotropic metric tensors in the formulation of structural tensors which enable various interactions and couplings between principal material directions [2]. The model contains only 3 stiffness-related material properties for glass-PTFE fabrics which makes it a competitive replacement of the commonly used linear elastic formulation.

To enhance the model response in numerical simulations a new framework is proposed to adjust and identify material properties based on the stress ratios appearing in structural problems. To this end, initially, the material parameters are separately adjusted to classical biaxial tensile tests with varying load ratios, e.g., 1:1, 0.5:1, etc., and additionally rather uncommon stress ratios 1:0.125, 1:0.75, etc. In a second step, an iterative simulation procedure will be applied, where, according to the locally obtained stress ratios within the discretized structural problem, the corresponding parameter values are updated at each integration point. The parameter values for stress ratios in between the experimentally measured ones are computed using a proper interpolation scheme. The iterative scheme is repeated until the overall parameter change on all points becomes negligible.

Aside from this approach, a more directly data-based procedure is proposed which already allows the description of the membrane's nonlinear response by still considering the linear-elastic model. For this, depending on the current local stress-ratio and stress intensity, a set of elastic constants of the linear elastic formulation is identified from a suitable interpolation scheme directly using the experimental data. Thereby, a continuously increasing cloud of computed material properties is used as the reference to update the locally varying stress-strain relation. Finally, both methods are compared with more classical approaches in realistic structural problems.

Abstract

Direct FE^2 [1, 2, 3] is a computationally attractive [4] FE^2 implementation as both the macro and micro-scale can be run in a single finite element analysis. The method is versatile as the in-built constitutive material models in a commercial FE software can be deployed easily to model any behaviour of the material micro-structure constituents and can be implemented on any commercial FE software that supports Multi-Point Constraints.

The Direct FE^2 method, models composite laminates using micromechanical single ply Representative Volume Element (RVE) [5,6]. The non-linear shear and damage behaviour of angled ply laminates is studied and simulated with the Direct FE^2 approach. Angled ply laminates are focussed since their non-linear behaviour arises from matrix plasticity and fibre reorientation in addition to constituent damage. This bottom-up approach needs only constituent (matrix and reinforcement) properties as input, thus eliminating the requirement for time consuming and expensive laminate and ply-level mechanical properties characterization. Matrix micro-cracks and fibre fracture are simulated using cohesive zone models. The results of the angle ply laminate simulation are compared with experiments. The fibre rotation observed in the various Direct FE^2 laminate models is also compared with existing model predictions. The Direct FE^2 simulation capability of composite structures is demonstrated by applying the method to model an angle ply laminate composite pipe (subjected to tension, torsion and bending) [6] from the constituent level and compared with experiments.

Key Words: *Particle Method, Polymer Matrix Composites, Compression Molding, Bead-Chain Model*

Compression molding is suitable for producing complex-shaped polymer matrix composite components owing to its short cycle time and low costs. In the method, the mold cavity is charged with the molding material using the two-part mold system, and the component is produced by fluidizing the material using a press machine. The components made by compression molding are susceptible to the uneven distribution of the resin and fibers. It is easy to occur short shots in the rib structure when producing the structure by compression molding. The strength and stiffness of the components are highly affected by the fiber distributions. To control the mechanical property of the molded components, it is essential to understand the various phenomena in the molding process.

The distribution of fiber orientations is affected by the molding process. Therefore, the multiphase flow analysis of fibers and resin is needed to understand the whole process of compression molding. Moving particle simulation (MPS) is suitable to explicitly model the fibers and resin using particles. The fiber orientation distribution and resin rich areas in injection molding of short-fiber-reinforced composites were predicted using the MPS method [1,2]. However, these previous studies assumed that the fibers are rigid. The elastic fibers that can be stretched and bent are required in compression molding of the rib structure because the fibers should be deformed at the entry and the tip of the rib.

This study develops the three-dimensional multiphase flow analysis considering the resin flow and the elastic fiber deformation. MPS is used to explicitly model the resin and fibers. The simplified bead chain model proposed by Sasayama et al. [3] is adopted to consider the fiber stretching and bending deformations. To verify the proposed analysis, the three-dimensional compression molding analysis of the cross-ply composite rib structure is conducted. The numerical results showed that the fibers bent when flowing into the rib and that the ply structure was maintained. These predicted phenomena qualitatively agreed with the experiments [2].

Key Words: *CFRP, Process-induced deformation, Multiscale analysis, Molecular dynamics, Finite-element analysis, quantum-chemical reaction path,*

Four-scale analysis composed of a quantum-chemical reaction path calculation, a curing molecular dynamics (MD) simulation[1, 2], a microscopic finite-element analysis (FEA), and a macroscopic FEA was developed to predict manufacturing process-induced deformation of composite laminate.
In this approach, thermomechanical properties, volumetric shrinkage due to curing reaction, and gelation point of matrix thermoset resin were predicted first by using MD simulations coupled with quantum calculations. Orthotropic material properties and cure-shrinkage deformation of unidirectional laminae were then evaluated by periodic unit-cell (PUC) analysis [3] using microscopic FEA based on the values obtained in the MD simulations. Finally, process-induced deformation of asymmetric cross-ply laminate due to cure and thermal shrinkage was predicted by macroscopic FEA analysis in which each layer of the laminate was modeled as an orthotropic homogeneous body by homogenization in PUC analysis. The predicted warpage of asymmetric laminates by using the presented multiscale analysis and experiments were in good agreement. In addition, the effects of the matrix resin species on the macroscopic deformation behavior were explored from the viewpoint of molecular scale using this multiscale analysis.
The results presented here provide important knowledge for the development of high-performance composite parts and stable manufacturing.

Key Words: *CFRPs, Open-hole tensile/compressive tests, Finite element analysis*

Stress concentrations around small holes (for fasteners) in carbon fiber reinforced plastics (CFRPs) have been studied for decades, especially in aerospace. Open-hole tensile (OHT) and compression (OHC) strength is a determining factor in the design of composite structures. The hole triggers stress concentrations and inherently reduces the net section volume. OHT and OHC testing is a prerequisite to leverage the use of composites in load-bearing structural applications. In the design of aircraft structural components using composite materials, it is necessary to verify all the factors that directly affect the strength (such as stress concentrations around holes as mentioned above), but due to the diversification of types of damage and failure due to the complexity of the structure, attempting to verify all of these by testing results in a significant increase in development costs and a longer development period [1]. For these reasons, in recent years, virtual testing has been attracting attention, which attempts to replace the certification test of CFRP laminates with numerical simulation [2]. Here, we forcused on the advanced CFRP laminates such as flame-retardant thermoset CFRP and investigated the stress-strain response of the OHT and OHC specimens. Furthermore, mesoscale fracture behavior of CFRPs are discussed by a finite element analysis.

In recent years, the eXtended Finite Element Method (XFEM), which can model cracks independently of the mesh, has been proposed and is applied to the damage progression analysis of CFRPs. In this study, mesoscale failure analysis of open-hole laminates is carried out for CFRPs. Matrix cracks in the layers and delamination between layers are the main damage mechanism, so XFEM is used to model matrix cracks independently of the mesh, and delamination is modeled by inserting interface elements between layers. The parameters for the XFEM model were determined based on the experimental results for uniaxial tensle/compressive tests and in-plane shear tests. Then, the prediction accuracy of the presented method is verified by predicting the progressive damage and strength, and comparing it with the experimental results of OHT and OHC tests. The effects of the matrix properteis on the transverdal tensile/compressive strangth and shear strength were also discussed by periodic unit-cell analysis.

Key Words: *Multiscale Modelling, Fiber Reinforced Composites, Shear-Flexible Beam Elements, Direct FE^2, Multi-Point Constraints*

Modelling fiber reinforced composites with high fidelity finite element (FE) analyses has always been challenging due to the large separation of length scales between a composite part and its constituent details. Current available computational resources put a limitation on the amount of details that can be modelled simultaneously. This means that important microscale mechanics such as fiber-matrix interactions may not be adequately captured when fiber reinforced composites are modelled at the part level or even at the ply level.

Multiscale modelling methods present an opportunity to marry these analyses across different scales by utilising the separation of length scales. Multiple analyses at different scales can be performed on the same problem to provide a more accurate prediction, while scale transition relationships are enforced between them such that the analyses remain consistent.

Here, a multiscale homogenisation model for fiber reinforced composite beams that is based on the novel Direct FE^2 framework will be presented [1]. At the part scale (macroscale), the computational efficiency of shear-flexible beam elements will be tapped upon. Its constitutive responses are provided by concurrent microscale analyses performed using explicitly modelled representative volume elements (RVE) of the composite. This reduces the computational cost to a fraction of that required in a true high fidelity analysis, making it much more feasible.

Scale transition relationships are enforced using multi-point constraints, which are readily available in most FE software. Kinematic downscaling of the macroscale loads is done by imposing appropriate periodic boundary conditions onto the RVE. On top of this, a separate constraint is required to impose the RVE shear angle, which has been successfully achieved via a weighted integral constraint. Kinetic upscaling of the microscale responses is done by appropriately scaling the RVE mesh volume. The scaling factor is governed by the Hill-Mandel homogenisation condition and Gaussian quadrature, and is imposed such that the strain energies across all the RVEs sum up to the corresponding macroscale value they represent.

In contrast to the more well known classical FE^2 approaches, Direct FE^2 offer a much simpler implementation for this multiscale framework. A generic, transferrable Python script is used to set up the model, presenting the opportunity for even users less experienced in multiscale modelling to utilise it. Beyond composites, the framework can be applied to a wide range of problems, as long as the base materials are known and an appropriate RVE can be constructed. Furthermore, this framework can be readily expanded to plate elements for flat composite structures as well.

Key Words: *Homogenization method, Phase-field method, CFRTP, Crystallization*

In recent years, the application of carbon fiber reinforced thermoplastics (CFRTPs) in aircraft structures has been broadening. Although they are mainly applied to the secondary structural components so far, they are expected to be applied to the primary structure in near future. The advantages of CFRTPs are their short manufacturing time, weldability, and recyclability. However, it is well known that their structural performance significantly depends on the manufacturing condition because the morphology of thermoplastic polymer is developed depending on the manufacturing (solidification) process. So far, many experimental studies have been performed on the cooling-rate dependent morphology and resultant mechanical properties of thermoplastics [1-3]. However, to the best of authors' knowledge, there is no numerical model and simulation scheme which is able to predict the performance of structural components made of CFRTPs from their manufacturing condition.

The objective of this study is to establish a numerical scheme to predict the structural performance of CFRTP components based on the manufacturing condition. The proposed scheme consists of two simulations; phase-field simulation and homogenization simulation. Firstly, the phase-field simulation [4-6] is performed to predict the morphology development (i.e., crystallization) of thermoplastics based on the solidification condition. Then, the homogenization simulation on the predicted morphology is carried out to predict the mechanical properties of CFRTP. The proposed scheme is verified against the experimental degree of crystallinity, rate of crystallization, and the resultant mechanical properties.

Key Words: *Nonlinear buckling, post-buckling, collapse, thin-walled structures, finite elements*

The composite thin-walled lenticular tubes (CTLTs) have been proposed as one of the most promising candidates for solutions of various light-weight large-scale deployable structures such as solar sails and wrapped-rib antennas in space[1]. Since the thin-walled tubes or booms are thin in thickness and have long aspect ratio, structural instability arises as one the biggest concerns for structural designs. This paper presents some numerical investigations on the nonlinear buckling, post-buckling and collapse behavior of the CTLTs subjected to pure bending[2]. First, an automatic implicit finite element (FE) simulation scheme accounting for high geometric nonlinearity was proposed for accurately predicting the nonlinear critical buckling load and the corresponding nonlinear buckling modes, as well as the postbuckling response of CTLTs. Next, an explicit dynamic finite element procedure was developed to analyze the quasi-static bending collapse of CTLTs. The effect of cross-section shapes on the performance (i.e., bending stiffness, nonlinear critical buckling load, and collapsing load) of CTLTs was highlighted through a parametric study performed on a variety of geometric configurations with the same weight but different cross-section shapes. The outcome of this work would enhance the understanding of nonlinear buckling, post-buckling, and collapse behavior of CTLTs, and open the door for cross-section shape design of CTLT structures.

Key Words: *Ultrasonic welding, Numerical simulation, CFRP.*

Carbon fiber reinforced plastics are widely used in the aerospace industry because of their superior specific strength and stiffness. Although thermoset composites have been mainly used in the past, thermoplastic composites have been attracting attention in recent years from the viewpoints of moldability and productivity. Thermoplastic composites have excellent impact resistance, recyclability, and short processing time. In addition, the characteristics of thermoplastic resin can be utilized for welded joints. By assembling components without using bolts or rivets, it is possible to reduce weight and stress concentration. One type of welding is ultrasonic welding. Ultrasonic welding is a method of welding by melting resin using the heat generated by transmitting vibration energy to the welding interface, and it can be done in a short time at normal temperature and pressure with energy saving[1]. However, the process parameters such as welding pressure, welding time, amplitude, and frequency are intricately related, and it is difficult to predict the optimum setting of these parameters, so the method has not yet been generally applied[2].

In this study, the temperature rise during the ultrasonic welding process was simulated and compared with the results measured experimentally. In the simulation of ultrasonic welding, the ultrasonic vibration is on the scale of 10^{-5} s, while the welding time is on the scale of 10^{0} s. The difference in the time scales causes a long calculation time. In this paper, we propose a multi-time-scale simulation method that can simulate the weld process with high accuracy and short calculation time. In the multi-time-scale simulation, the temperature rise per microsecond at each initial temperature of 25°C is calculated in the microsecond-scale simulation. Then, normal-scale simulation, in which the ultrasonic vibration is replaced by a constant load, is used to simulate the entire ultrasonic welding process accurately by fitting the microsecond-scale simulation with the material properties as variables. In the ultrasonic welding process, a neat polymer protrusion called an energy director (ED) is inserted between the materials to be welded. The ED acts as a starter for softening and melting of the resin, and enables stable welding. Focusing on the ED, we investigated the effect of the shape on the temperature rise. The results of the study showed that the slope of the temperature rise was close to the simulation results obtained by multi-time-scale simulation. The energy dissipation due to viscoelasticity was found to be important in the temperature spike. It is also shown that the temperature spike is caused by stress concentration above a certain level.

Key Words: *Self-deployment, Finite Element Analysis, Experiment, Plain Weave Composite, Strain Energy Distribution, Transitional Configuration*

Various deployable booms have been developed because simplicity, light weight and high storage efficiency are required for space deployment structures. One of them is an open sectional boom which is made of Carbon Fiber Reinforced Plastic (CFRP) plain weave composite molded into a cylindrical beam shape. This boom has a characteristic of having two different stable states, showing bistability. In the deployed state and the coiled (stored) state, it retains each shape without any external force or constraint. Once the triggering deformation is imposed to the coiled state, this boom autonomously transforms to the initial cylindrical beam shape.

It is observed that the deployment of the bistable beam may come to halt in the transitional state, and detailed analyses of the mechanism are required. Although Brinkmeyer et al. [1] introduced and considered the deployment force, it was evaluated without identifying various factors such as friction or air resistance. In addition, the decrease of the deployment velocity is investigated only on experimental basis, whereas the finite element analyses focus on the shape and deformation during the deployment in detail.

In this study, a series of the transitional configuration from the coiled shape to the deployed shape was simulated by finite element analysis. Rectangular plate specimen was used to directly measure the stiffness matrices (ABD matrices) that are used in the FE analysis. In order to consider the heterogeneity of fiber bundle in the plain woven fabric composite, the in-plane stiffness (A matrix) was obtained from the tensile test, and the out-of-plane stiffness (D matrix) was calculated from the result of the bending test and the torsion test. In the coiled state, the distribution of strain and curvature is generated in the cylindrical axis direction under the influence of the free edge. With reference to Fujioka et al. [2], self-deployment force is defined as the reaction force generated when a fixed rigid wall prevents the bistable beam from self-deploying. In addition, for each deployed length, the strain energy of whole bistable beam was calculated. It is found that the rate of change of strain energy with respect to the deployed length is equal to the reaction force of the rigid wall. To evaluate the validity of finite element analysis, experimental investigation is conducted and the self-deployment force were measured with the same method. The finite element analysis and experiment results show that the self-deployment force gradually increases as the bistable beam deploys, and converges to a constant value after a certain deployed length. The critical deployed length can be estimated from the strain energy distribution in the longitudinal direction.

Steady-State Creep Analysis of Composite Spherical Vessels Using the Finite-Strain Theory

Vinod K. Arya
Professor of Mathematics
University of North Texas at Dallas
Dallas, Texas, USA
(vinod.arya@untdallas.edu)

Keywords: Composites, Spherical Vessels, Steady-State Creep, Finite-Strain Theory

ABSTRACT

The paper presents the steady- state creep analysis of spherical vessels of particulate composite materials using the logarithmic strain (finite-strain) theory. The paper develops (in an almost closed form) expressions for the stress and strain distributions in the spherical vessels. The stress and strain distributions are evaluated numerically at various radii of the spherical vessel and the results are displayed graphically. The effects of the particulate size on the stress and strain distribution are studied for several different particulate sizes and the results are exhibited graphically. Finally, the results from the present investigations are compared with the results for a spherical vessel of monolithic materials and the differences in the stress and strain distributions in the two types of the spherical vessels are clearly brought out. It is believed that the results from this research will aid the designers in selecting a spherical vessel of a material that will be most useful in meeting their requirements.

Composite materials have been widely used in various fields. Composites have superior mechanical properties such as specific rigidity or specific strength, but mechanical responses of composite structures have larger dispersions comparing to conventional homogeneous materials. In particular, a lot of stress concentrations due to non-homogeneous and not-perfectly controlled microstructure will be observed, and therefore stress analysis considering its inhomogeneity and a stochastic analysis considering microscopic random variations have been attracted [1]. In using finite element method for the analysis, one of the problems is difficulty when considering geometric randomness such as random fiber arrangement in fiber reinforced plastics (FRP).

For this problem, the Mesh Superposition Method[2] is attempted to be employed for the analysis, since the numerical model for the analysis can be easily generated even for materials with complex internal structures. In this research, an improved mesh superposition method-based analysis approach is developed for stabilizing the analysis of composites[3] based on the M^3 Method[4], and it is applied to stochastic stress analysis of unidirectional FRP considering random variations of fiber location. In the previous report[3], effectiveness of the presented approach is validated when fiber volume fraction (Vf) was assumed to be relatively low, and the relatively small location variation was considered.

In this report, for more realistic composites, the stochastic stress analysis of FRP with high Vf and large variation using the improved mesh superposition method is attempted, and the effectiveness and problems in the analysis will be discussed with some numerical examples.

[2] Kindai University, 3-4-1 Kowakae Higashiosaka Osaka Japan, sakata@mech.kindai.ac.jp

Key Words: *Peridynamics, Composites, Fracture analysis, In-situ observation, Strength*

In this presentation, stress analysis of a unidirectional fiber reinforced composite material by coupling peridynamics and in-situ observation is discussed for apparent strength estimation of the material. Composite materials have complex microstructures and complex damage propagation caused by multiple cracks originating from the interface between the reinforcement material and the base material. For this analysis, for example, XFEM based approach or analysis using the cohesive element has been attempted, but the complexity and difficulty of these approaches, further effort for more efficient approach to analysis is needed. Furthermore, the apparent strength of the composite material varies due to the randomness / uncertainty of the microstructure. Therefore, in-situ observation is important for the accurate representation of the real material model and from the viewpoint of Verification & Validation. From this background, we attempted to employ the peridynamics method [1] to the stress analysis of composites and in-situ observation using a digital microscope. In this method, the formulation is based on integral equations and the target object is spatially discretized by particles, and it will be more effective for modelling and solving problems involving many inclusions and discontinuities such as cracks than conventionally used analytical methods such as finite element method. For the in-situ observation, the status of an actual composite specimen during tensile testing is accurately observed using a digital microscope [2].

Firstly, outline of the problem setting, peridynamics and in-situ observation are explained. Some numerical results on the stress analysis of the fiber reinforced composite plate under transverse tensile load by in-situ observation-aided peridynamics analysis are shown. Validity and effectiveness of the analysis based on the coupling of peridynamics and in-situ observation for composite material are investigated, and applicability of the method to the analysis of a fiber reinforced composite material is discussed.

Key Words: *Structural Analysis, Multiscale Analysis, Lattice Structures, Mechanical Metamaterials*

Mechanical metamaterials are artificially manufactured materials with properties, which cannot be obtained from natural materials, consisting of deliberately designed microscopic internal structures [1]. Those conceptual artificial materials are ready to fabricate with the advent of the additive manufacturing technology. Recently, a class of metamaterials has been actively studied due to its potentials for performance improvements and extensions of structural capabilities. Mechanical metamaterials can exhibit exotic material characteristics and/or macroscopic behaviors attributed to their micro/mesoscale internal structural designs such as truss or porous in μm/mm order in addition to material properties constructing the structural components. For example, metamaterials having unique properties such as zero Poisson's ratio, ultralight weight less than 0.01 g/cm^3, simultaneous lightweight and high stiffness (approximately 700 kg/m^3 and 1 GPa) are hoped to realize high-performance structures [2].

In this paper, structural characteristics of lattice-based mechanical metamaterials will be studied. The objectives of this paper will be 1) to develop an analysis framework, which enables structural evaluations to design mechanical metamaterials, 2) to demonstrate the feasibility of the methodology to evaluate structural characteristics of lattice-based mechanical metamaterials, and 3) to explore and study the potential and structural integrity of lattice-based mechanical metamaterials.

In order to efficiently model such structures, a computational homogenization method for lattice-based mechanical metamaterials capturing characteristics of a representative unit cell is implemented. A unit cell of the periodically distributed structure is modelled as representative finite elements, and the equivalent stiffness properties of the unit cell are calculated based on the computational homogenization procedure. The obtained equivalent stiffness properties are used to perform a multi-scale structural analysis of lattice-based mechanical metamaterials. Similarly, stress amplification factors recovering a stress distribution in a microlattice structure based on a macroscopic stress distribution, which is obtained from the multi-scale structural analysis, will be calculated with the present finite element procedure. A microscopic stress distribution recovered based on stress amplification factors will then be used for strength evaluation.

Key Words: *CFRP, Lightning strike, Multiphysics Problems, Industrial Applications*

Carbon fiber reinforced plastic composites (CFRP) have been applied to primary structures of aircrafts with the aim of improving fuel efficiency because of its mechanical property. Aircrafts are sometimes struck by lightning in flight, resulting in damage of structures. Once the surfaces of CFRP structures are damaged, inspection and repair are required. To reduce the lightning strike damage, it is important to clarify the damage mechanisms caused by lightning strike. Lightning strike damage are caused by complex physical and chemical phenomena such as Joule heat generation, thermal decomposition of matrix resin, breakdown, combustion, acoustic force, electro-magnetic force and others. Because of the complexity of the phenomena, the effects of each phenomenon on lighting damage are not understood in detail. Objective of this study is to understand the effect of Joule heat generation on lightning strike damage with lightning current test. The static and impulse lightning current was directly applied to CFRP specimen by performing conduction tests to avoid the effect of arc root behavior and acoustic force. Temperature response was measured by using a thermal camera. Finite element analysis was conducted to estimate joule heating effect caused by lightning current.

CFRP laminates were fabricated from unidirectional carbon fiber/toughed epoxy prepreg tapes (IMS60/133, Toho Tenax Co. Ltd., Japan). The stacking sequence were $[0]_{16}$ (16 plies). A specimen had 10 mm width, 50 mm length and 2.2 mm thickness. Lightning current was applied with an impulse current generator (Haefely Hipotronics). Component A waveform in accordance with SAE ARP 5412B was applied to an electrode which was connected directly to edge of specimen. The other electrode, which was directly connected to edge of specimen, was connected to ground. The maximum current peak value was 10 and 20 kA. Lightning strike phenomena were captured by using a high-speed camera (Shimadzu Corp.) and a thermal camera (FLIR Systems, Inc.). As results, pyrolysis gas at the side surface was observed immediately after the current injection. Changing temperature distribution state over time was successfully obtained by a thermal camera. Temperature response estimated by finite element analysis showed good agreement with experimentally obtained results.

Key Words: *Natural Fibers, Anisotropy, Unidirectional Composite, Numerical Analysis*

Concerns about the environmental situation, namely pollution and wasteful use of fossil fuels, have generated a great demand for the development of new environmentally friendly materials for use in various fields. Natural fiber-reinforced composites are seen as a good alternative to traditional synthetic fiber composites. However, for natural fiber composites to be an adequate replacement, they must demonstrate sufficient mechanical strength, especially for load-bearing engineering components or structures. This study investigated the strength of materials composed of unidirectional sisal fibers (grown in the Negev region of Israel) within a thermosetting polymer matrix, containing 20%, 40% and 60% fiber volume fraction. Experiments in conjunction with finite element modeling were utilized to determine the effective mechanical response and failure modes of the composite for the different material compositions. Tensile tests on the composites were performed with loading along the fiber and at an angle of 45° to the fiber direction. Tensile testing along the fiber direction was also carried out on specimens with holes and notches for various fiber volume fractions. Assuming the unidirectional composite behaves as a transversely isotropic material [1] with an anisotropic fiber, both analytical [2] and micro-mechanical numerical models were used to estimate the effective mechanical properties as a function of the sisal volume fraction, and a comparison was made with the experimental results. A macroscopic approach was used to simulate the tensile tests. During the simulation, the parameters of the damage evolution were determined, and the parameters of damage initiation were validated. Finite element analysis was carried out using Abaqus™ software. The study shows that the behavior of sisal fiber reinforced composites is linear elastic prior to failure. The average longitudinal modulus of elasticity of the sisal fibers is 25 GPa, the average tensile strength of the fibers is 490 MPa with a strain at failure of 1.5-2%. The fiber transverse modulus of elasticity determined by finite element analysis is 1.6 GPa. It was observed that failure form depends on the volume fraction of the fibers; in materials containing a smaller amount of fiber, a localized failure band perpendicular to the direction of the fibers occurs, while for materials containing a greater amount of fiber, failure in the form of splitting along the fibers takes place. The results of this study shows that materials with sisal fibers can reach tensile strength of 250 MPa, which are comparable to high strength aluminium and thus can be used in structural applications. The simulation results are in good agreement with the experiments.

Key Words: Tapered composites, ply drops, localised 3D stresses, Unified formulation

Wind turbine blades often vary in thickness throughout to optimize local strength and stiffness. Changes in thickness of laminated composite structures results in ply drops, where the number of through-thickness plies of a composite structure suddenly changes. Ply drops represent sudden changes in not just geometry but also material properties. Both can cause stress concentrations leading to structural failure [1]. In order to minimise the effect of local stress concentrations, they should not be positioned in stressed areas.

Although closed-form solutions exist for the stress state in ply drops, they do not replicate the complex non-linear behaviour and the interactions between ply drops. Current work uses a novel variable kinematics continuum finite element to model the tapered laminate structure with high accuracy. Based on the Unified Formulation (UF), the element uses a hierarchical, Serendipity-Lagrange expansion based model to describe the kinematic field.

Previous work using this element considered prismatic structures solely consisting of hexahedron shapes. Modelling composite structures with a layer-wise approach has shown high accuracy using this approach [2]. However, modelling ply drops requires using other elements, such as wedge elements. Modelling non-hexahedron geometries is achieved by collapsing nodes, similar to degeneration of element formulations in conventional finite element analysis.

Tapered composite panels featuring multiple ply drops are analyzed. The results will include direct comparisons between the formulation and conventional finite element models. Early work has already shown excellent agreement in the stress fields with a significant ($\sim$ 4x) reduction of the degrees of freedom.

Key Words: *Ductile fracture prediction, cold forging, finite element analysis, anisotropic damage*

Researchers have formulated equations of ductile fracture to simulate and predict defects in cold-forged parts, e.g., the Cockcroft–Latham criterion [1]. However, these equations are not applicable to certain cases of fracture in forged products. This study formulates a new equation for predicting ductile fractures with better prediction accuracy than the convention by which cost for trial-and-error design can be reduced.

The equation is expressed as a second-rank symmetric tensor, which is the inner product of the stress and strain-increment tensors. The theoretical efficacy of the equation in predicting ductile fractures is verified via a uniaxial tensile test.

The practicability of the equation is confirmed by applying it to the simulations of two real cold-forged components: a cold-forged hollow shaft and a flanged shaft. For the hollow shaft, the equation predicts the position where the ductile fracture would initiate, which—to the best of the authors' knowledge—is unique to this study. For the flanged shaft, the equation predicts the occurrence of diagonal cracks due to different lubrication conditions.

Key Words: *CDM, Ductile failure, FEA*

In order to properly characterize failure limits for metallic materials, the scientific community has developed numerous failure criteria. These criteria can in general be classified into two different categories: criteria that differentiate between damage initiation and damage evolution, and criteria that do not. Currently, there is no agreement in the scientific community regarding the most accurate criterion when it comes to predicting damage initiation and/or evolution. Many of the ductile failure criteria incorporate some triaxiality dependent plastic strain measure as a governing parameter for ductile failure initiation. Nevertheless, to the best of the authors' knowledge, a study, dedicated to investigating the accuracy of different criteria on the specific ductility of a material has not been conducted. It could be that a certain criteria are valid only for limited values of ductility.

In this study, experiments in conjunction with computational analyses were conducted in order to investigate the influence of the materials ductility on the failure prediction capabilities of different failure criteria based on the Continuum Damage Mechanics (CDM) approach. Two different aluminum alloys with different levels of ductility were selected Al7075-T651 and Al2024-T351. Compression experiments on three different specimen geometries were conducted. The displacement and strain fields were measured using Digital Image Correlation (DIC). Each specimen geometry resulted in a unique triaxiality-plastic strain relation up to initial failure. Finite element models of the experiments were developed and used to study the deformation process upto and including failure. The models underwent a standard solution verification process and validation against the DIC and the force-displacement measurements. The computations were used to quantify the different parameters required in order to determine failure initiation and evolution for the various criteria examined (stress, strain and energy density based criteria). The computational-experimental methodology reported in [1] and based on [2] was used to generate a damage initiation failure curve for each alloy. An energy based damage evolution criterion was implemented in order to model damage evolution and crack propagation. Finally, three point bending experiments on bars with complex geometries were conducted in order to test the different criteria against data which was not used in the initial parameter identification process.

Key Words: *Numerical Method of Ductile Fracture, Damage Evolution, Damage Level Definition, Void Shape Effect*

Numerical simulation has increasingly become an extremely significant tool to predict ductile fracture and is of great significance for engineering application. Ductile fracture includes void nucleation, growth and coalescence at micro level. Therefore, a reliable damage model based on void evolution is an effective part of numerical method to investigate ductile fracture.

A novel damage level was given and defined as the ratio of the maximum statistical cross-sectional area of voids to the cross-sectional area of the representative elements. Void nucleation is continuous in the whole deformation process [1], which was described by statistical theory in our investigation. Under arbitrary load condition, void growth includes not only volume change but also shape change [2]. Combined with the void number continuous equation, a novel damage evolution model including void nucleation, volume change and shape change was derived. Based on the proposed damage evolution model, a series of numerical simulations were conducted on tensile fracture of aluminum specimens under different loading state. The effects of specimen shapes on stress state, strain state and void number distribution were summarized by numerical simulations. The corresponding numerical predictions were verified by the experimental results under the same load and a good agreement was obtained between numerical and experimental results. The consistency of comparison clarifies that the presented novel damage evolution model is reliable.

The numerical predictions include both shear fracture and tensile fracture with different levels of stress concentration. All predictions agree well with experiments both from macroscopic fracture morphology and microscopic void distribution of the fracture. The parameters involved in this model can be directly obtained by experiments and it made the application of this model simple. Such definition of damage level in our model has clear physical meaning and requires no additional critical damage level to characterize failure. The numerical simulation with such damage model is a powerful numerical method to analyze ductile fracture under different stress states. Such numerical method provides a convincible theoretical support for engineering design.

Predicting Ductile Fracture during Sheet Stretching by a Modified Miyauchi Test Using an Ellipsoidal Void Model

Kazutake Komori[1*]

[1] Department of Mechanical Systems Engineering, School of Engineering, Daido University

Key Words: *Ductile Fracture, Void Model, Sheet Stretching, Miyauchi Test, Prestrain*

Ductile fracture is a microscopic phenomenon because it occurs through nucleation, growth, and coalescence of voids. Since the ductile fracture criteria that are widely used for metal-forming processes, such as those introduced by Cockcroft and Latham, Brozzo et al., and Oyane, are derived from a macroscopic viewpoint, it is challenging to improve the prediction accuracy for a microscopic ductile fracture phenomenon using a macroscopic ductile fracture criterion. Although nucleation and growth of voids are simulated in the Gurson model, the coalescence of voids cannot be simulated intrinsically. Hence, for instance, the coalescence of voids is assumed to occur when the void volume fraction reaches a critical value. However, this assumption is inappropriate, because the critical void volume fraction depends on the stress state. Hence, the coalescence of voids should be evaluated using a model with a definite physical meaning.

The author has attempted to predict ductile fracture during metal-forming processes from a microscopic viewpoint [1]. The author's proposed model of void coalescence is based on the two-dimensional void model proposed by Thomason and that proposed by Melander and Ståhlberg, which are also derived from a microscopic viewpoint. Both the Thomason model and the Melander and Ståhlberg model assume that the void is rectangular and that the direction of the major axis of the void coincides with the direction of the maximum principal stress. In contrast, the author's proposed model assumes that the void is ellipsoidal and that the direction of the major axis of the void does not coincide with the direction of the maximum principal stress. Hence, the author's void model can be used for simulating metal-forming processes.

In this study, an ellipsoidal void model [1], which has been proposed by the author, is evaluated by the sheet stretching using a modified Miyauchi test [2], which was originally proposed to evaluate the relationship between the shear stress and the shear strain. A number of experimental researches on the prediction of ductile fracture during the sheet stretching have been performed. However, few researches on the effect of prestrain on ductile fracture have been performed. Hence, in this study, the effect of prestrain, which is applied to a sheet by rolling, on ductile fracture during the sheet stretching, has been clarified numerically and experimentally.

Keywords: Two-dimensional peridynamics equation of motion; absorbing boundary condition; corner reflection.

The aim of this paper is to construct accurate absorbing boundary conditions (ABCs) for the two-dimensional peridynamics equation of motion which describes nonlocal phenomena arising in continuum mechanics based on integrodifferential equations. To this end, a full discretization of the system is used based on a Crank-Nicolson scheme in time and an asymptotically compatible scheme in space. Recursive relations for the Green's functions are then derived and numerically used to evaluate the nonlocal ABCs. In particular, these absorbing boundary conditions solve the corner reflection problem with high precision. The stability of the complete fully discretized scheme is stated and numerical examples are finally reported to demonstrate the validity of the resulting ABCs.

Component-wise fracture analysis through coupled three-dimensional peridynamics and refined one-dimensional finite elements

Peridynamics (PD) is a non-local theory introduced by Silling in [1]. It is based on integro-differential equations, which means that PD could be employed for the investigation of problems with discontinuities, such as cracks. Nevertheless, the computational cost of a full 3D peridynamics analysis could be prohibitive. For this reason, researchers are working on coupling of local elasticity with peridynamics (i.e. [2,3]), in order to exploit the features of both theories. This work investigates crack propagation problems by combining local and non-local elasticity models. Specifically, the portion of the domain where the failure takes place is modelled via 3D peridynamics. On the other hand, the remaining part of the domain is modelled via refined 1D elements through the Carrera Unified Formulation (CUF) [4], which in recent years has proven to provide 3D-like results with a significant reduction of the computational cost. The coupling between the two domains is realized through the introduction of Lagrange multipliers, as presented in [5]. The present work is an extension of a previous one [6], where fracture in brittle material solid specimens was investigated through sequentially linear analysis. Particular attention is focussed on the crack propagation in multi-component structures (e.g., thin-walled reinforced structures) and multi-scale problems.

Key Words: *Crack propagation analysis, Peridynamics, Embankment, Seismic response analysis*

An earthquake can induce the failure of soil embankments owing to the initiation and propagation of several cracks caused by extension stress and shear stress in these embankments. To improve the earthquake resistance of soil embankments, it is crucial to clarify the crack initiation and propagation processes. Peridynamics, a nonlocal formulation theory of continuum mechanics introduced by Silling [1], is a powerful method for such analyses. For applying seismic-response analysis to ordinary state-based peridynamics (OSB-PD), Shimbo et al. [2] formulated the seismic response analysis for crack propagation analysis using OSB-PD.

In the present study, a crack propagation analysis of a compacted clay embankment during an earthquake was performed. The physical parameters of the compacted clay were obtained via uniaxial compression tests with an initial crack. The compacted clay was assumed to be a linear isotropic elastic material with a bulk density (ρ_t) of 1761 kg/m^3, the Young's modulus (E) value of 8.5 MPa, a Mode II Fracture toughness (K_{IIC}) of 6.2 kPa.$\sqrt{}$m, and a critical stretch (S_c) of 0.0018. The input seismic wave was a sinusoidal wave with a frequency of 1 Hz and a maximum acceleration of 300 Gal, and the acceleration gradually increased according to the envelope curve. The analytical model used was an embankment-only model with a slope of 1:1.25, a height of 5 m, a crown width of 5 m, and a bottom width of 20 m. The bottom of the analytical model had a fixed boundary conditions in the horizontal and vertical directions. In the embankment-only model, the horizontal stress due to gravity was eliminated using the viscous boundary condition. In the present analysis, the seismic waves were input from the bottom of the analytical model after the stress distribution due to gravity was stabilized. To confirm that the stress distribution due to gravity was stable, the stress distribution was calculated using kernel interpolation.

The analysis of crack propagation during earthquakes shows typical failure patterns of embankments during the earthquakes, such as cracks in the slope and shear failure (i.e., a sliding surface) caused by the crack initiation and propagation.

Dual Horizon Peridynamic Implementation in a Finite Element Framework - ANSYS

Sundaram Vinod K. Anicode[1] and Erdogan Madenci[2*]

[1]University of Arizona, Tucson, AZ USA, sundaramanicode@email.arizona.edu
[2]University of Arizona, Tucson, AZ USA, madenci@email.arizona.edu

Key Words: *Peridynamics, Dual-horizon, Non-uniform mesh, Finite elements, ANSYS*

This study presents a finite element framework to perform a dual horizon bond-based (BB), ordinary state-based (OSB) and non-ordinary state-based (NOSB) peridynamic (PD) analysis in ANSYS, a commercial software, with native MATRIX 27 elements. Especially in large-scale models, a non-uniform PD discretization leads to computational efficiency. However, non-uniform mesh with a varying horizon causes spurious wave reflections and ghost forces between the PD points due to the assumption of uniform horizon in the derivation of BB and state-based PD equilibrium equations [1, 2]. Ren et al. [3] introduced the concept of dual horizon PD to consider non-uniform discretization with a varying horizon. The PD equilibrium equations are satisfied only at points with a complete horizon. Otherwise, they are not satisfied at points with an incomplete horizon even for a homogeneous displacement field. This also results in residual forces leading to kinks and unphysical stress concentration near the boundaries. In order to remove this limitation, the domain can be split into three regions: interior, outer and boundary layer regions. The dual horizon BB, OSB and NOSB equilibrium equations can be considered at every point in the interior region with a complete horizon. The PD differential operator (PDDO) [4] or PD least square minimization (PD LSM) [5] form of the equilibrium equations and the traction components can be considered at a point with an incomplete horizon in the outer and the boundary layer regions. These equations permit the direct imposition of both displacement and traction boundary conditions in the boundary layer region. In each region, MATRIX27 elements native to ANSYS are employed to model PD interactions (bonds). The coefficients of the MATRIX27 element are expressed in terms of PD functions. Failure is introduced gradually as suggested through the EKILL option in ANSYS. The accuracy of the approach is demonstrated by considering a plate with or without a crack under tension subjected to various types of boundary conditions.

Dual-horizon peridynamic element and its coupling with finite element

Yehui Bie[**], Yueguang Wei[*]

Department of Mechanics and Engineering Science, College of Engineering, Peking University, Beijing 100871, PR China

Abstract

The peridynamic theory redefines the mechanical problems in terms of integral equations rather than partial differential equations, which makes it mathematically compatible with crack initiation and propagation. However, the surface effect and high computational consumption of peridynamics certainly limit its application. To make peridynamics widely available for numerical scientists and engineers, a potentially valuable method may be the integration of the PD and its coupling with FEM within the finite-element commercial software, such as Abaqus. To implement peridynamics in Abaqus, the dual-horizon peridynamic element is proposed and constructed in Abaqus/UEL. Correspondingly, the dual-horizon peridynamic element internal force vector and element stiffness matrix are derived and constructed. To implement the coupling model of PD and FEM in Abaqus, a unified variational weak form is proposed based on the convergence of peridynamics to the classical model in the limit of vanishing horizon. Since the integrals of the dual-horizon peridynamic element (DHPDE) and finite element in this dual-based coupling method are completely decoupled in the viewpoint of numerical implementation, which makes it easier to realize the adaptive coupling by switching integral element. Several numerical examples involving the static and dynamic crack propagation are investigated and the satisfactory results show the availability of the dual-horizon peridynamic element and its coupling with finite element. The implementation of DHPDE in Abaqus can fit into any existing computing platform and can be parallelized conveniently, which may make it easy for researchers and engineers to model engineering crack propagation in Abaqus.

Key Words: *Fracture analysis, Peridynamics, Stress intensity factors, Shear deformation*

Ordinary state based peridynamic theory (OSPD), as one of the meshfree method, is widely applied in the fracture analysis nowadays. However, it has shown less accuracy in the simulations of shear behaviours in the fracture analysis. Therefore, a modified OSPD is introduced to improve the performance of the original theory. Different from original bond kinematics, deformations induced by bond rotation are taken into consideration. Meanwhile, the rigid body rotation (RBR) of the bond is also determined and removed from the total displacement with the help of peridynamic differential operator (PDDO) technique. The modified OSPD is tested by several typical benchmark problems. Stress intensity factors (SIFs) are evaluated by employing J-integral method. The numerical solutions of these cases are validated by the reference results provided in the literature and original OSPD. Good agreements of the solutions between the modified OSPD and reference methods can be derived. Meanwhile, the improvements in the mode-II fracture analysis have also proved accuracy and reliability of the proposed formulation in the simulation of shear fracture behaviours.

Key Words: *Peridynamics, Porous media, Wave propagation, Micro-cracks*

Peridynamics [1] is a new continuum mechanics formulation. As opposed to partial differential equations of classical continuum mechanics, peridynamic equations are in integro-differential equation form and do not contain any spatial derivatives. Therefore, peridynamics is very suitable to analyse problems with discontinuities such as cracks. Moreover, peridynamics has a length scale parameter called horizon which allows representing non-local effects which cannot be captured by using classical continuum mechanics. There has been significant progress on peridynamics research especially during the recent years [2,3].

In this study, wave propagation in porous media subjected to impact loading is investigated by using ordinary state-based peridynamics. Moreover, the effect of micro-cracks on wave propagation is examined by changing the number of micro-cracks and their orientation. It is observed that depending on the micro-crack configuration, wave propagation can be significantly influenced due to the existence of micro-cracks.

Peridynamic Simulations of Gas-pore Effects on Fatigue Lifetime

LIU Binchao [1,*], CHEN Bocai [2], ZENG Weipeng [3] and BAO Rui [4]

[1] Beihang University, Beijing, 100191, China, kidvictor-liubc@buaa.edu.cn

[4] Beihang University, Beijing, 100191, China, rbao@buaa.edu.cn

Key Words: *Peridynamics, Fatigue lifetime, Gas pore, Additive Manufacturing*

Additive manufacturing (AM) becomes increasingly attractive in a wide range of industries, but it remains a tough task to understand its unique fatigue performance, which is mainly due to its intrinsic meso-defects such as gas pores and lack-of-fusions. Due to the complex impacts of interactive mechanisms between mechanics and materials, it is difficult to reveal the impacts by experiment or mechanical analysis. As an attempt, peridynamics (PD) is adopted in this paper to numerically study gas-pore effects on fatigue lifetimes of 2-dimensional smooth specimens.

While the computational costs of modeling meso-defect by reducing material point sizes for the smooth specimen is unacceptable, it is necessary to develop a multiscale modelling approach to map the meso-defect effects onto the upper scale. Thus, a strategy is developed by decomposing an origin PD bond into many sublevel bonds, and the status of PD bond can thus be more elaborately described as “how much works” rather than dualistic judgement of “broken or not”, whose capabilities are verified by comparisons with FEM results.

Combining such strategy with PD fatigue damage-cumulative model [1], numerical simulations are performed to reveal the gas-pore effects on fatigue lifetimes; to be specific, the gas-pore is approximated as circular meso-defect with three radius cases of 20,50,100μm, and its location varies from surface roughness to subsurface and to the interior. It is shown that the gas-pore location and size exert interactive impacts on fatigue lifetimes: a larger defect is of course more dangerous, but the threshold size below which the gas-pore effects on fatigue lifetimes is dependent on its specific location, and subsurface gas-pore is always the most dangerous place. To be more specific, data distribution degree of fatigue lifetimes is decided by gas-pore sizes, while data distribution shape of fatigue lifetimes is decided by gas-pore locations.

To conclude, this work provides a PD-based procedure as well as guidelines for AM processing optimization and understanding of meso-defect effects on fatigue lifetimes of AM materials. In the future work, more features such as defect shape, defect orientation and defect numbers can be considered, and the method can be extended to 3D cases.

Simulation of Brittle/Quasi-brittle Fracture with the Smoothing Gradient Damage Model

Chanh Dinh Vuong*, Tinh Quoc Bui and Sohichi Hirose

Tokyo Institute of Technology, 2-12-1-W8-22, Ookayama, Meguro-ku, Tokyo 152-8552, Japan
(E-mail addresses: vuong.d.aa @m.titech.ac.jp)

Key Words: *Brittle fracture, Quasi-brittle fracture, Gradient enhanced damage, FEM*

We present two fracture problems, anisotropic fracture and failure in rock-like materials. In the first part, we introduce a novel smeared gradient-enhanced damage model [1, 2] which takes into account directional-dependent damage evolution in two-dimensional polycrystalline materials. In details, the cleavage fracture in polycrystalline materials is considered. In terms of the recently developed smoothing gradient damage model [1, 2] for isotropic localized failure analysis, we introduce a new damage evolution equation to capture anisotropic fracture. Theoretically, directional fracture properties are integrated with the damage evolution equation through a second-order structural tensor [3]. The efficiency of proposed damage model is demonstrated through numerical experiments. The second part focuses on the analysis of mixed-mode fracture process of rock-like materials. For this problem, a novel equivalent strain formulation, developed in [4], is modified and integrated into the smoothing gradient damage model [1, 2]. We consider several popular rock fracture problems.

Key Words: *Peridynamics, Contact analysis, Dynamic fracture, Particle Method*

Peridynamics, one of particle method, has advantages for several fracture problems. On the other hand, many particles are required to ensure accuracy, compare with mesh based method, such as Finite Element Method. Furthermore, conventional peridynamics has the limitation that the horizon, range of influence function, should be same values. it leads the particles size is equal on entire model.

The variable horizon approach which supports the varying horizon, particle size, was proposed. However, the ghost force problem was detected. The ghost force is the discretization error, and it arises along the transition region of different horizon.

We have proposed smoothed variable horizon peridynamic model to reduce the ghost forces and it is adopted in this study.

In this study, the smoothed variable peridynamic concept extends to the contact model. The contact forces, short-range force in PD, was re-defined for varying horizon and the re-formulated the governing equation.

The Hertz problem is examined, and the numerical result converged to the theoretical. In addition, the computational cost was significantly reduced with variable horizon contact peridynamic model.

A variational phase-field model for subcritical fracture

Juan Michael Sargado[1]*, Michael Welch[1] and Mikael Lüthje[1]

[1] Danish Hydrocarbon Research and Technology Centre, Technical University of Denmark
Elektrovej 375, 2800 Kongens Lyngby, Denmark
E-mail: jmiuy@dtu.dk

Key Words: phase-field, subcritical fracture, stress corrosion

We present a variational phase-field framework for modeling subcritical crack growth in geological materials. Also known as static fatigue, this phenomenon is characterized by the occurrence of crack extension at stress levels substantially below those associated with the critical energy release rate, G_c. We assume that this is brought about mainly by stress corrosion, in which highly stressed material at crack tips is weakened due to chemical reactions in the presence of an environmental agent. Prior studies in the literature point to the existence of a nominal value of the energy release rate, G_0, below which subcritical crack growth does not occur. Above this threshold, the speed of crack extension can be related to the crack tip energy release rate via a power relation known as Charles' Law.

Following recent phase-field approaches for modeling fracture due to cyclic fatigue [1, 2], we incorporate the aforementioned behavior in the variational phase-field framework by scaling G_c with a function whose time rate of change depends on a quantity analogous to the energy release rate. Apart from the displacement and phase-field variables already present in the standard model for brittle fracture, no additional field unknowns are introduced in connection with static fatigue. Instead, an ordinary differential equation must be solved to determine the critical energy release rate evolution at each material point. The coupled system is solved numerically using a hybrid discretization that utilizes classical finite elements for the linear momentum conservation and cell-centered finite volumes for the energy balance governing phase-field evolution [3, 4].

Modelling the evolution of large fracture networks

Michael Welch[1*], Mikael Lüthje[1]

[1] Danish Hydrocarbon Research and Technology Centre, Danish Technical University, 2800 Kgs Lyngby, Denmark. mwelch@dtu.dk, https://www.oilgas.dtu.dk/english

Key Words: *Fracture modelling, Linear Elastic Fracture Mechanics, subcritical propagation*

Geomechanical simulation of fracture growth is a useful technique for predicting fracture density, distribution and geometry, with important applications in geomechanical engineering and subsurface flow modelling. However fracture networks developed across large geological structures (e.g. km-scale folds, faults or diapirs) may contain hundreds of thousands or even millions of individual fractures, so it is impractical to simulate each fracture directly.

We have therefore developed a method to apply basic geomechanical laws governing fracture propagation to cumulative density distribution functions which represent the fracture population as a whole. In this way, we can model the evolution of these functions through time without needing to create realisations of the individual fractures in the network. We use this method to model the evolution of layer-bound fracture networks across large geological structures. We assume that brittle layers such as sandstone or limestone beds contain an initial population of small microfractures. As a deformational strain is applied to the layer, a stress concentration will develop around the fracture tip which can be calculated by Linear Elastic Fracture Mechanics theory [1]. This will cause the fractures to grow, at a rate predicted by subcritical crack propagation theory [2]. Eventually the fractures will reach the top and bottom layer boundaries, after which they will grow laterally as elongated layer-bound fractures. By applying the fracture propagation rate equations to the cumulative density distribution function representing fracture density as a function of size, we can model the evolution of these functions through time [3, 4].

For a simple model with uniform and constant strain, we can derive analytical solutions, but for more complex models with laterally and temporally variable strain, we can discretise the model into cells and timesteps. As the fractures grow, they will interact, and we must include the effects of these interactions. We include two types of interaction in our model: intersection between perpendicular or oblique fractures, and stress shadow interactions between parallel fractures. The rate of fracture interaction is dependent on the fracture population, so this will also evolve through time. We calibrate the results of these models by comparing the resulting cumulative density distribution functions with those derived from dynamically generated DFNs.

Non-linear phase field models are increasingly used for the simulation of fracture propagation problems. The numerical simulation of fracture networks of realistic size requires the efficient parallel solution of large coupled non-linear systems. Although in principle efficient iterative multi-level methods for these types of problems are available, they are not widely used in practice due to the complexity of their parallel implementation.

Here, we present Utopia, which is an open-source C++ library for parallel non-linear multilevel solution strategies. Utopia provides the advantages of high-level programming interfaces while at the same time a framework to access low-level data-structures without breaking code encapsulation. Complex numerical procedures can be expressed with few lines of code, and evaluated by different implementations, libraries, or computing hardware. In this presentation, first we illustrate a globally convergent solution strategy designed to solve non-convex constrained minimization problems [1]. Second, we provide an overview of its implementation [2], and provide an overview of its parallel performance. Third, we provide examples of pressure-induced phase-field fracture propagation in large and complex fracture networks. Solving such problems is deemed challenging even for a few fractures, however, here we are considering networks of realistic size with up to 1000 fractures.

Key Words: *Magneto-electro-elastic (MEE) material, Crack, Interaction integral (I-integral), Thermal loading, Intensity factors*

Magneto-electro-elastic (MEE) materials, consisting of piezoelectric and piezomagnetic constituent phases, have received special attention from the research community owing to their specialized performance and coupled behavior under thermal, electric, magnetic and mechanical loads [1]. However, reliability issues due to fracture during service in the thermal environment still remain a major factor preventing their further development during service in the thermal environment. Complex interfaces between different constituents cause a great challenge to the fracture analysis of MEE materials [2]. In this work, considering the effect of the thermal loading, an interaction integral (I-integral) method [3] for an impermeable crack is developed to extract the crack-tip fracture parameters including stress intensity factors, electric displacement intensity factor and magnetic induction intensity factor of homogenous, nonhomogeneous and multi-interface MEE materials. Combined with the extended finite element method, the I-integral is adopted to solve several crack problems to show the accuracy and validity of the method. The influences of crack-face thermal boundary conditions, crack inclination angle and crack length are analyzed in homogeneous MEE material. Then, the I-integral values calculated by different integration domains agree well with each other for nonhomogeneous and discontinuous material properties. Besides, good results show the effectiveness and the domain-independence of the present method in the fracture analysis of nonhomogeneous and discontinuous MEE materials. In view of the wide applications of MEE materials in various thermal environments, the present analysis could serve as a reference for the design of various smart structures of MEE media.

Mixed finite-element formulations for flexoelectricity in piezoelectric solids with analysis of fracture behaviour

Prince Henry Serrao and Sergey Kozinov*

Ruhr-Universität Bochum, Universitätsstr. 150, 44801 Bochum, Germany.
corresponding author: sergey.kozinov@rub.de, http://www.lkm.rub.de/institut/team/kozinov.html.de

Key Words: flexoelectricity, fracture mechanics, strain gradients, higher order theory, mixed FEM

Piezoelectricity is an important phenomenon observed only in certain classes of dielectrics. Conventional electromechanical coupling is restricted to material with a non-centrosymmetric unit cell structure. As an alternative, the flexoelectric effect is observed in all dielectrics and is prominent at micro- and nanoscales. Flexoelectricity is an electromechanical coupling between electrical (mechanical) quantities and strain (polarization) gradient. Flexoelectricity is a suitable substitute for piezoelectricity for electromechanical coupling and can be used for applications in nanosensors, actuators, high precision devices, etc.

Traditional continuum models lack material length scales which were introduced by Cosserat using strain gradients and significantly extended by Mindlin [1]. Strain Gradient Elasticity (SGE) theory results in fourth-order partial differential equations demanding C^1 continuous elements for traditional FEM to be used. To avoid such difficulties, mixed-FEM is used as formulated by Amanatidou [2] for SGE problems and later extended to flexoelectricity in dielectric solids by Mao [3] presenting I9-87 element (87 DOF).

In our work, a piezoelectric contribution is considered in addition to pure linear dielectric material in the formulation of flexoelectricity. This allows to clearly separate the influence of the piezoelectric and flexoelectric electromechanical coupling. As a particular case, when neglecting piezoelectric contribution, our results simplify to that of [3]. Additionally, in the vicinity of sharp tips (presence of cracks or defects), naturally occurring inhomogeneous strain distribution induces strong polarization even under the influence of a weak electric field. Our solution was implied for the crack problems, studying the mutual influence of the piezo- and flexoelectric contributions on the fracture parameters within the framework of the linear elastic fracture mechanics.

Key Words: *Ferroelectrics, Fracture, Dielectric breakdown, Domain switching, Phase field model, Generalized configurational force*

Ferroelectric materials have attracted increasing attention due to their distinguished electromechanical performance. In the presence of mechanical and electrical loadings, the failure behaviours of fracture and dielectric breakdown may occur simultaneously in ferroelectric materials. Understanding the coupling evolution of fracture, dielectric breakdown and polarization is crucial for the application of ferroelectric materials under complex electromechanical environments. In the present study, a phase field model is developed to investigate the coupling evolution behaviour of polarization, fracture and dielectric breakdown in ferroelectric materials subjected to the mechanical and electrical loadings. Different degradation functions are proposed to model different interface boundary conditions for fracture and dielectric breakdown. Generalized configurational forces for fracture and breakdown are derived from the phase field model to analysis the driving forces for the coupling evolution. Under a set of interface boundary conditions, interactions between fracture and dielectric breakdown are investigated systematically. The phase field simulations show that dielectric breakdown can be induced by the concentrated electric field at impermeable crack tips. At the same time, the dielectric breakdown can influence the stress distribution around the crack tip as well as the driving force for crack propagation. The attraction of fracture to breakdown path and the deviation of breakdown to fracture path are observed simultaneously during the coupling evolution of fracture and breakdown. The results in the present work provide an insight into fracture and breakdown coupling failure mechanism in ferroelectric materials. The developed model framework can be employed to investigate more complex coupling failure behaviours of ferroelectric and dielectric materials.

Configurational Mechanics for Modelling Fracture Propagation in Heterogeneous and Anisotropic Materials

Chris Pearce[1*], Karol Lewandowski, Ignatios Athanasiadis and Łukasz Kaczmarczyk

[1] Glasgow Computational Engineering Centre, University of Glasgow, Glasgow G12 8QQ, UK, Chris.Pearce@glasgow.ac.uk, www.glasgow.ac.uk/gcec/

Key Words: *Fracture, Configurational Mechanics, Heterogeneous Materials*

A mathematical formulation and numerical modelling framework for brittle crack propagation in heterogeneous elastic solids is presented. The formulation is developed in the framework of configurational mechanics and solved numerically using the finite element method.

The proposed model is based on the assumption of maximal dissipation of energy and uses the Griffith criterion. We show that this is sufficient to predict crack propagation in brittle heterogeneous materials, with spatially varying Young's modulus and fracture energy, and for anisotropic materials. The configurational forces and fracture energy release rate are both expressed exclusively in terms of nodal quantities, avoiding the need for post-processing, and enabling a fully implicit formulation for modelling the evolving crack front and creation of new crack surfaces.

For heterogeneous materials, it is shown that it is necessary to have a spatially smooth density field, with higher regularity than if the field is approximated directly on the FE mesh. Therefore, density data are approximated as a smooth field using a Moving Weighted Least-Squares method. For functionally graded materials, the density fields were generated analytically. Fracture in bone is also investigated, with density fields determined from clinically available CT scan data.

The proposed formulation is verified and validated by comparing numerical results with both analytical solutions and experimental results. Both the predicted fracture path and load–displacement response show very good agreement with experiments.

albin.wessling@ltu.se

Key Words: Bonded Discrete Element Method - Rock Fracture - Heterogeneous

Numerical modelling of the fracture of heterogeneous brittle materials is of interest for several industries, such as rock excavation and comminution applications. A numerical model of brittle materials needs to be able to capture the unpredictable results, e.g. with regards to measured strength and fracture pattern, as observed experimentally. In a previous work [1], the Bonded Discrete Element Method [2] was combined with statistical methods in order to generate heterogeneous rock bodies. Grains of random sizes and shapes, consisting of multiple bonded discrete elements, were generated in the body and the micromechanical parameters of these grains were governed by the Weibull distribution [3]. In this work, this modelling approach was used to evaluate the fracture behaviour of experiments commonly found within the field of rock mechanics - the unconfined and confined axial compression test, Brazilian disc test and the three point bend test. For each test, a large set of numerical samples were generated and simulated. The fracture behaviour, e.g. initiation, propagation and coalescence of cracks, were investigated for different levels of heterogeneity and grain cement strengths. The results show that a variety of different fracture modes can be obtained with this modelling approach. Further, the results suggests that the statistical methods employed in this work improves the versatility of the Bonded Discrete Element Method for rock modelling.

Surrogate-based stochastic optimization for enhancing interfacial fracture resistance of heterogeneous structures

Sukhminder Singh*, Lukas Pflug and Michael Stingl

Chair of Applied Mathematics (Continuous Optimization),
Friedrich-Alexander-Universität Erlangen-Nürnberg,
Cauerstraße 11, 91058 Erlangen, Germany
E-mail: *sukhminder.singh@fau.de

Key Words: Interfacial Fracture, Surrogate-based Optimization

Recent developments in the field of computational modelling of fracture have opened up possibilities to design structures against failure. A special case, called interfacial fracture, can occur in loaded heterogeneous structures where two or more materials are bonded together at comparatively weak interfaces. Due to the presence of unstable crack growth along interfaces, the structural problem suffers from high nonlinearities and instabilities, leading to noisy and discontinuous responses. In such a case, local-gradient-based optimization approaches are not feasible due to lack of analytical sensitivities and also due to the presence of spurious local optima (minima). In this work, we use a stochastic optimization approach to maximize the expected value of the mechanical work done by external loads under uncertainties in the design parameters, distributed normally. To overcome the intractability of Monte-Carlo methods for the estimation of the expected value of the expensive-to-evaluate response function, an approximate global Voronoi-piecewise surrogate [1] is constructed using a few initial randomly generated samples. The surrogate function is refined successively in each optimization iteration by adding samples in a small region in the design space close to the current iterate. A local minimum of the expected value of the surrogate then results in the next design point. For the stochastic optimization of cheap-to-evaluate surrogate function, a Newton-type algorithm is used. Promising results show that by taking a large sampling region in the beginning of the optimization run and gradually decreasing it helps to overcome spurious local minima and leads to a robust final design. We show the effectiveness of the proposed framework with the help of optimization examples with up to 12 design degrees of freedom, where the shape parameters of the heterogeneities are optimized for interfacial fracture resistance. Finally, we show that the performance of the optimization algorithm can be significantly improved by reducing the dimensionality of the stochastic variables while keeping the dimension of the design parameters the same.

Unified definition of stress intensity factors of a sharp three-dimensional jointed corner among dissimilar anisotropic materials

Toru Ikeda[1*], Omar Ibrahim[1] and Masaaki Koganemaru[1]

[1] Department of Mechanical Engineering, Graduate School of Science and Engineering, Kagoshima University, 1-21-40 Korimoto, Kagoshima, Kagoshima 890-0065, Japan, ikeda@mech.kagoshima-u.ac.jp

Key Words: *Three-dimensional corner, Jointed anisotropic dissimilar materials, Eignevalue, Eigenfunction, Scalar parameters, Stress intensity factor*

In the manufacture of electronic devices and micro-electro-mechanical systems (MEMS), a wide variety of materials are jointed. For light-weight automobiles, CFRP materials are jointed with metallic materials. In these products, jointed interfacial corners are singular stress points from which fractures sometimes originate.

Evaluating the severity of singular stress fields is important for protecting these corners from fracture. In our previous studies, we proposed a definition of the stress intensity factors (SIFs) of two-dimensional (2D) jointed interfacial corners [1, 2]. We can use this SIFs formula to evaluate the singular stress field around a jointed interfacial corner with a smooth edge front in a three-dimensional (3D) object.

However, fractures sometimes occur from sharp 3D jointed corners. In our previous paper, we proposed a numerical method for calculating the scalar parameters (SPs) that describe the singular stress fields around sharp 3D corners [3, 4]. The SPs are the coefficients in William's Eigenvalue expansion form that express the singular stress field around a sharp notch or crack. In this study, we propose a unified definition of SIFs at sharp 3D jointed corners between anisotropic dissimilar materials. These SPs can describe the singular stress field, but they are not adequate as the fracture mechanics parameters which evaluate the fracture from such a corner.

In this study, we propose a new definition of the SIFs of a sharp 3D corner. The definition is compatible with the SIFs of 2D corners, of interfacial cracks and of cracks in uniform material. Furthermore, the proposed SIFs can describe the singular stress along any directions around a sharp 3D jointed corner.

Key Words: *3D Fracture Simulation, Meso-Scale, Numerical Experiment, Coarse Aggregate, Concrete, Damage Model*

Numerical experiments are carried out for reinforced concrete in 3D meso-scale. The reinforced concrete model reflects the geometry of deformed bars and coarse aggregates in detail. The damage model based on fracture mechanics of concrete is applied to crack propagation analysis of concrete and the von-Mises plasticity model is applied to the elastic-plastic analysis of steel [1]. The numerical experiments are compared to actual experiments performed in a laboratory. These results show good agreements, implying that the numerical experiments proposed in this study are physically reasonable.

The numerical experiment consists of a non-linear finite element analysis and 3D meso-scale reinforced concrete model. The finite element analysis with non-linear material models is first formulated. The modified von-Mises damage model based on fracture mechanics of concrete [2] and the standard von-Mises plasticity model are applied to the constitutive law of concrete and steel, respectively. The modelling of 3D meso-scale reinforced concrete is second explained. In particular, the detailed geometry of deformed bars and coarse aggregates is reflected in 3D. The 3D complicated spatial arrangement of coarse aggregates is also reproduced in detail.

We finally show numerical experiments of reinforced concrete beams with or without shear reinforcements to verify the availability of the proposed model. The numerical results are compared to experimental results performed in a laboratory. The comparison demonstrates that the numerical responses are in good agreement with those obtained experimentally. In addition, these results confirm that the failure modes simulated in the numerical experiments provide good fits to the experimental data.

Key Words: *3D cohesive zone model, Friction, Steel-concrete interface, Pull-out test*

It is essential to model the behavior of the interfaces between steel reinforcement and concrete in order to understand the stress transfer between these two components in reinforced concrete structures. The interface models commonly used include several parameters whose identification is based on pull-out tests, for which sensitivity to a number of parameters is not fully explained [1]. In this contribution, the steel-concrete interface is studied at the mesoscopic scale through the simulation of pull-out tests. The three dimensional numerical reinforced concrete samples are generated by applying the procedure described in [2], in which each sample is made up of concrete surrounding a ribbed or smooth bar embedded in the center of a cubic sample. The detailed geometry of the ribs of the steel bar is modelled with different possible shapes. Then, the finite element code Cast3M [3] is used to perform the pull-out numerical simulations on the generated samples, using Mazar's damage approach [4] with regularization to describe cracking in concrete. The steel-concrete interface is modelled by combining a modified cohesive zone model (CZM) based on Tvergaard's approach and a frictional model accounting for the frictional behavior in the damaged part of the interface. This is done by modifying the 2D approach described in [5] and generalized to 3D in [6], by replacing the Crisfield's damage model by the more adapted Tvergaard's model and modifying the corresponding stresses to account for its exponential behavior. The interface is divided into an undamaged part where the CZM model applies and a damaged part where the frictional model dominates. The total stress is then the addition of the two corresponding stresses, and is equivalent to the CZM stress when the interface is initially undamaged, and fully equivalent to frictional model's stress when the joint element is finally fully damaged. The overall response is studied in terms of the damage near the steel bar, the applied force versus displacement curves, and free end displacements. The results of mean bond stress versus the free end displacement are compared to available experimental data.

Key Words: *Variational formulation, Thermally induced crack, Concrete, Thermo-mechanical coupling, Continuum damage mechanics*

Fracture phenomena of concrete have been investigated in various aspects, and many models have been developed to predict crack initiation and propagation under a variety of mechanical and/or environmental conditions. In particular, thermo-mechanical coupled problems have seen some standard formulations for thermally induced cracking in concrete, but as far as we know, not yet been formulated as a variational problem based on fracture mechanics. To this end, in this study, a novel variational formulation for thermally induced cracking in concrete is originally presented. Specifically, we formulate the variational problem for a continuum damage model based on fracture mechanics that is coupled with heat conduction and realize thermally induced cracking phenomena in concrete by implementing it in our finite element (FE) code.

As the first step, we define a Helmholtz energy function and a damage "yield" function based on the isotropic damage model proposed by Kurumatani et al. [1] that is consistent with the conventional cohesive zone model. Next, in line with Canadija & Mösler [2], a functional of total energy rate and its optimization problem is formulated to obtain the equilibrium state of concrete. Finally, optimality conditions are established to derive the weak form and the load/unload conditions for damage evolution and heat conduction. After the suitable discretization for time and space within the FE framework, the resulting equations are properly implemented. The capability and merit of proposed formulation against the convetional formulation by presenting representative numerical examples to predict the thermal-induced cracking in concrete structures.

Key Words: high performance concrete (HPC), steel-fiber reinforcement, phenomenological material model, elasto-plastic phase-field model, three-point bending beam test, degradation of residual stiffness

High performance concretes (HPCs) have attracted a great interest in the construction industry worldwide because of its wide variety of applications. The dense microstructure of HPCs and additional reinforcement of steel fibers gives high strength and superior durability, see [2]. These additional fibers restrain the further growth of crack by transmitting the stresses from concrete matrix to fibers during fracture which affects the deterioration characteristics of concrete in cyclic flexural tests, see [3]. On this account, within DFG priority program 2020 (SPP 2020), strong research is focused on the experimental and numerical analysis of failure of HPC under fatigue. In this contribution, a phenomenological material model is developed combining the superposed models of transversal isotropic elasto-plasticity, see [1] and a continuum phase-field model based on the variational formulation of fracture in elasto-plastic material, cf. [4, 5, 6]. Two different data driven degradation functions for the modeling of unique behavior of HPC in tension and compression are calibrated by simulating the typical uniaxial cyclic tests. The numerical model is calibrated and validated by comparing the numerical results of three-point bending beam test at low cycle for pure and reinforced HPCs to experimental data, see [7].

Study on Damage Characteristics of Ceramsite Concrete Based on Multi-phase Mesoscopic Model

Xiaoqiang Yan[1*], Rixing Huang[1], Xiaoxiao Sun[1], Nana Zhang[1], and Xiaoming Guo[1]

[1] School of Civil Engineering, Southeast University, Nanjing, China, 230198099@seu.edu.cn

Key Words: *Ceramsite Concrete, Multiphase Mesoscopic Model, Lattice Model, Interfacial Transition Zone, Damage analysis*

As a novel building material, lightweight ceramsite aggregate concrete has been widely used in the construction of high-rise buildings, long-span bridges, and marine structures in harsh environments as the obvious advantages in its lightweight, good thermal properties, fire resistance, and seismic resistance as well as environmental friendliness. In this paper, a lattice model for mesoscale modelling of heterogeneous materials was proposed, and the mesoscopic damage mechanism of ceramsite concrete was studied. The mesoscopic multiphase lattice model was established by mapping the random aggregates model onto the random disordered grid, and the correctness of the model was verified by comparing it with the experiment. Based on the Mazars damage constitutive relation, the damage failure mechanism of ceramsite concrete was studied. The damage of ceramsite concrete first occurred in ceramsite as the ceramsite aggregate was the weakest composition in ceramsite concrete composite, which is different from the damage first appearing in the interface transition zone of ordinary concrete. Then, the damage evolution of ceramsite concrete could be expressed as: with the application of load, the damage appeared discretely in a number of ceramsite aggregates and involved into micro cracks in some aggregates. As the applied load continued to increase, the damage gradually developed to the ITZ and cement mortar area. When the applied load reached its peak, the damages began to fuse and initially developed into a macrocrack. With further loading, the macrocrack developed rapidly as the damage evolution intensified around the macrocrack while relieved in the other region.
The proposed multi-phase mesoscopic lattice damage model can accurately calculate the whole deformation and failure process of concrete at a low cost, especially, the proposed model can effectively simulate the strain-softening and damage localization of concrete materials.

Abstract

A time-domain method for modeling three-dimensional dynamic fracture using high-order elements [1] of the scaled boundary finite element method (SBFEM) is presented. The scaled boundary finite element method can simplify the modeling of cracks and extract the dynamic stress intensity factors directly from sigular stress field around the crack tip, which shows great potential for fracture analysis [2,3]. The spectral element approach [4] and hierarchical polynomial shape functions [5] are applied to generate the high-order shape functions of elements. The mass and stiffness matrix of high-oder elements are derived based on the high-order shape functions [6,7]. The three-dimensional equation of motion are established and solved by using the Newmark method. Linear ealstodynamic fracture mechanics is used to define the dynamic stress intensity factors (DSIFs) [8], which are directly extracted from the dynamic response at each time step. A benchmark problem is investigated to validate the accuracy of high-order elements. Numerical results demonstrate that both the p-refinement and h-refinement can improve the computational accuracy of the DSIFs. It is proven that higher rate of convergence is obtained using p-refinement instead of h-refinement.

University of New South Wales, Sydney, Australia
[1] ankit@unsw.edu.au, [2] junqi.zhang@unsw.edu.au, [3] c.song@unsw.edu.au,
[4] s.eisentraeger@unsw.edu.au

Key Words: *Octree mesh, Explicit damage analysis, Parallel computing, Scaled boundary finite element method.*

This work develops a massively parallel solver for performing explicit damage analysis of structures in three dimensions. To eliminate the mesh sensitivity due to strain localisation, an integral-type non-local model is implemented. The problem domain is discretised using balanced octree meshes. The repeating cell patterns are exploited for the pre-computation of element matrices leading to lesser memory requirements. The scaled boundary finite element method (SBFEM) is employed, which directly handles octree cells as polyhedral elements and eliminates the hanging nodes issue. To efficiently perform the matrix operations associated with solving equilibrium equations, an element-by-element (EBE) approach is utilised. Here, the reduced number of unique octree patterns are exploited to perform group-wise matrix computations, which avoids a global matrix assembly, allows better cache utilisation, and aids associated memory-bandwidth limited computations, resulting in significant performance gains. The parallelisation is carried out using the mesh-partitioning strategy and implemented using the message-passing algorithm. The developed computational framework can efficiently simulate large scale damage problems with more than a hundred million unknowns and allows for massive scaling with several thousand cores in a distributed computing environment.

A NURBS enhanced polygonal element formulation for the nonlinear analysis of solids in boundary representation

Rainer Reichel[1] **and Sven Klinkel**[1*]

[1] Lehrstuhl für Baustatik und Baudynamik, RWTH Aachen University, Mies-van-der-Rohe-Str. 1, 52074 Aachen, Germany

Key Words: Polygonal element formulation, Scaled boundary finite element method, Displacement elemnent formulation, Nonlinear solid mechanics

The contribution is concerned with a numerical element formulation for the nonlinear analysis of solid in boundary representation. Its results in a polygonal element with an arbitrary number of sides. Straight edges are possible as well as curved edges, which are described by e.g. Non-Uniform Rational B-Splines (NURBS).

The presented element formulation is based on the scaling concept, which is adopted from the so-called scaled boundary finite element method (SBFEM), see [2]. The SBFEM is a semi-analytical formulation to analyze problems in linear elasticity. Within this method the basic idea is to scale the domain's boundary with respect to a scaling center in order to describe the interior domain. In contrast to SBFEM, the proposed method uses a numerical approximation for the displacement response in scaling direction. This enables the analysis of geometrically and physicallly nonlinear problems in solid mechanics, see [1]. The interpolation at the boundary in circumferential direction is independent of interpolation in scaling direction. This allows the use of different basis functions for each direction, e.g. NURBS basis functions in circumferential and Lagrange basis functions in radial direction.

The advantage of the presented element formulation is the flexibility in mesh generation. For example, using Quadtree algorithms, a fast and reliable mesh generation can be achieved. Furthermore, in connection with trimming algorithms, the element formulation allows a precise representation of the geometry even with coarse meshes. Some benchmark tests are presented to evaluate the accuracy of the proposed numerical method against analytical solutions, and a comparison to standard element formulations is given as well.

A Scaled Boundary Finite Element Framework for Mesh Burden Alleviation and High-Performance Computing

Chongmin Song[1]

[1] University of New South Wales, Sydney, NSW 2052, Australia, c.song@unsw.edu.au

Key Words: *Scale boundary finite element method, Polyhedron element, Octree, High-performance computing, Explicit dynamics, Preconditioned conjugate gradient solver*

In the scaled boundary finite element method [1], an element is constructed semi-analytically. The boundary is discretized and the solution inside the element is obtained analytically. Within this framework, the element can take *any* shape and it only needs to satisfy a scaling requirement (i.e. there exist a point from which the whole boundary is directly visible). The scaled boundary finite element method provides a high degree of flexibility in terms of element shape and order. It has been shown to be highly complementary with the octree meshing algorithm. The combination is capable of significantly alleviating the mesh burden for not only the conventional CAD models but also digital images [2] and STL models [3]. The boundaries can be defined either explicitly by the elements or implicitly embedded within the elements [4]. It is found that the number of unique element patterns in an octree mesh is limited to a very small number and the operation of a matrix-vector product can be performed efficiently according to the patterns of the polyhedron elements on a high-performance computing (HPC) facility. The potential of this approach is demonstrated by an explicit time integration scheme [5]. Based on the same technique, a preconditioned conjugate gradient solver is developed for HPC. The implicit time integration scheme can be performed like an explicit scheme, retaining the advantages of both schemes. The extension to consider material nonlinearity is also addressed. Numerical examples are presented to demonstrate the concept and potential of the proposed framework.

A temporally piecewise adaptive extended multiscale scaled boundary finite element method for viscoelastic problems

Xiaoteng Wang, Haitian Yang, Yiqian He*

State Key Lab of Structural Analysis for Industrial Equipment, Department of Engineering Mechanics, Dalian University of Technology, Dalian 116024, P.R. China, Email: heyiqian@dlut.edu.cn

Key Words: *multi-scale; viscoelastic promble; temporally piecewise adaptive algorithm; numerical base function.*

This paper provides a new numerical method for solving multi-scale heterogeneous viscoelastic problems which is presented by combining the extended multi-scale scaled boundary finite element method and the temporally piecewise adaptive algorithm. In the time domain, temporally piecewise adaptive algorithm is adopted and the recursive equations for solving multi-scale viscoelastic problems are derived. When the time step changes, the computation accuracy in time domain can be guaranteed by adaptive calculation. In the space domain, the extended multi-scale scaled boundary finite element method based on numerical base function is used to solve the recursive equation and decrease the solution scale. The stress singularity can be easily and effectively dealt with. Combined with quadtree technique, the meshing of scaled boundary finite element based on image recognition is realized. The proposed approach provides a flexibility to increase macro scale nodes without increasing new nodes inside the coarse element and changing the shape of the fine grids according to the position of the increase macro nodes. The solution accuracy can be improved by such an increase. Numerical examples show that the proposed method has stable accuracy and can effectively improve the computational efficiency.

The identification of structural internal defects is an important research content of structural health monitoring. At present, the structural safety inspection based on non-destructive testing mainly focuses on qualitative analysis, so it is difficult to identify the scale of defects quantitatively. In this paper, an inversion model is proposed by combing the scaled boundary finite element methods (SBFEM) [1-2] and deep learning [3-4]. The identification of crack-like defects can be performed in structures based on the feedback signal of Lamb wave propagation. By randomly generating defect information, i.e. position and size, the SBFEM can be used to simulate the signal propagation process of Lamb wave in structures with defects. The SBFEM only needs to discretize the structure boundary, which can minimize the re-meshing process and greatly improve the computational efficiency. When Lamb wave propagates in a cracked structure, the feedback signal of the observation point can reflect crack information. Based on this characteristic, enough training data reflecting the characteristics of the problem can be provided for the deep learning model. The proposed defect inversion model avoids the iterative process of minimizing the objective function of the traditional inverse problems [5], and greatly reduces the computational cost on the premise of ensuring accuracy. Numerical examples of plates with single and multiple cracks are analyzed. The results show that the defect identification model can accurately quantify the defects in the structure. It also has a good identification effect for shallow cracks. The model also shows robustness to the noisy signal model.

Key Words: Differentiation, Guided Waves, Scaled Boundary Finite Element Method, Optimization

The task of frequency-dependent material parameter determination in the ultrasonic regime is established as an inverse problem relying on measurement and simulation data. The latter is provided by a forward model, which must be repeatedly evaluated; thus, a high-performance model is required. Especially in the case of cylindrical samples, the (axisymmetric) scaled boundary finite element method (SBFEM) provides a framework to derive such an efficient model. The number of degrees of freedom is reduced to a minimum by discretizing only along the radial direction while permitting the computation of bounded domains of arbitrary length [1].

The inverse problem is interpreted as an optimization problem w.r.t. the differences between measured and simulated mechanical displacement responses. While global optimization allows finding a global minimum, it requires an excessive number of model evaluations, and thus is not considered in this work. In contrast, given adequate initial parameters, local optimization, specifically gradient descent, is favored because it promises fast convergence. However, an accurate computation of gradients requires differentiation of the forward model with respect to the parameters that are to be determined.

In this contribution, we present the explicit differentiation of the SBFEM model via iterative application of the chain rule. We discuss the challenges faced in the differentiation of the Hamiltonian eigenvalue problem, which is an essential part of the SBFEM formalism [2]. Our method leads to a robust and efficient computation of gradient information far superior to the application of finite difference quotients.

Key Words: *Scaled Boundary Finite Element Method, Dynamic Crack Face Contact*

The static and dynamic contact problems of general structures have been widely studied. However, regarding crack problems, due to the singularity of the stress at the crack tip and the complexity of the dynamic contact on the crack faces, only a few studies have considered the dynamic contact on the crack face.

The scaled boundary finite element method is used to solve dynamic crack face contact problems. Ooi et al. [1] constructed bubble functions based on the displacement field that would be caused by polynomial body loads. The method is applied to the problem of crack side-face loads. The scaled boundary finite element (SBFE) shape function considering the side-face loads is used to derive the dynamic contact equation and the characteristic matrix related to the dynamic calculations [2].

The standard Newmark time integration algorithm is very successful in analyzing the conventional dynamic responses of structures, but its application in the Lagrange multiplier method meets some difficulties in dealing with dynamic contact problems effectively [3]. Especially when time step Δt is very small, the classical Lagrange multiplier method will give out the oscillatory field of contact forces. A modification of the classical Lagrange multiplier method is presented using a special time integration.Due to the introduced high-frequency dissipation in this time integration algorithm, this method can lead to the effective analysis of real response of elastic bodies with dynamic crack face contact constraints. The results show that this method has higher precision than the traditional Newmark time integration algorithm.

Key Words: *Domain Decomposition, Discontinuous piecewise-defined functions*

The current connotation of domain decomposition is to divide a global problem into several independent local problems to apply parallel computing. But in a broad sense, domain decomposition refers to a systematic way of introducing a partition, so that functions can be defined in each of its elements independently, thus generating a linear space of piecewise discontinuous functions. When working in these spaces, the problem to be solved is called the Boundary Value Problem with Prescribed Jumps (BVPJ) [2].

As a background, Dr. Herrera and his collaborators, based on an Algebraic Theory applied to Boundary Methods, which generalizes Green's formula to linear spaces of piecewise discontinuous functions, have developed two discretization methods [1]. The first one, called the Direct Method (or Poincaré-Steklov Method), arises from the weak formulation in terms of the data of the problem; while the second one, called Indirect Method (or Trefftz-Herrera Method), arises from the weak formulation in terms of the complementary data of the problem. The difference between them is the following. In the first one, local solutions of the homogeneous differential equation are developed in each element of the partition to construct specialized base functions called optimal base functions; while in the second one, local solutions of the homogeneous adjoin differential equation are developed in each element of the partition to construct specialized weight functions called optimal weight functions. In practice, the optimal functions are approximated with numerical methods; for example, Collocation Methods.

In this work, a novel method is presented that articulates the aforementioned methods by means of a dual decomposition of operators, which simultaneously uses the optimal base functions and the optimal weight functions. The dual decomposition of operators is determined by what is called the sought information from the solution in the interior boundary, which could be either the average of the function, or the average of its normal derivatives. This method has been called the Finite Element Method with Optimal Functions (FEM-OF), since the optimal functions are approximated with the conventional Finite Element Method. In this way a general basis for a theory of finite element methods in spaces of piecewise discontinuous functions is established. In the general literature, methods that use different spaces for base functions and weight functions are called Petrov-Galerkin Methods.

The FEM-OF method has a great generality because it can be applied either to linear differential equations or to systems of them. In this work, applications to the general second-order equation and linear elasticity equations are presented. FEM-OF has significant advantages over conventional FEM. Two of the main advantages are that FEM-OF reduces the number of degrees of freedom and that it exhibits superconvergence when applied to non-self-adjoint differential operators. Other advantages are that FEM-OF generates better structured matrices, it has a great flexibility to select the approximate polynomial spaces and, as already mentioned, that it can be applied without additional difficulties to BVPJ. In any case, FEM-OF has higher precision.

Key Words: acoustic scattering, on-surface radiation condition, isogeometric analysis, Non-convex scatterers, phase reduction

We develop Isogeometric on surface radiation condition (IGA-OSRC) method to solve acoustic scattering problem. First, we demonstrate the possibility of reducing the spatial dimension by one and alleviation of mesh burden using the proposed IGA-OSRC. Geometrical features were evaluated accurately even at very course discretization levels. The Pade-type OSRC was optimized to increase the accuracy of the proposed method especially at high frequency analyses. To avoid pollution error and enable dramatically fast analyses at high frequencies, we separate the oscillatory part of the solution and solve for slowly varying amplitude leading to development of phase-reduced IGA-OSRC (PR-IG-OSRC). We demonstrate the performance of the PR-IGA-OSRC method for two- and three- dimensional acoustic scattering problems and propose a coupling method to increase its accuracy for analyses of nonconvex scatterers. Hence, the proposed method reduces the meshing burden, increases the accuracy, and dramatically reduces the computational cost for the analyses of arbitrary shaped scatterers.

Modelling Creep in Short-Fibre Reinforced Composites Based on the Scaled Boundary Finite Element Method

Johanna Eisenträger[1*], Junqi Zhang[1], Sascha Eisenträger[1], and Chongmin Song[1]

[1] The University of New South Wales, School of Civil and Environmental Engineering, Sydney, Australia, j.eisentraeger@unsw.edu.au

Key Words: Creep, Scaled Boundary Finite Element Method, Rate-Dependent Inelasticity, Image-Based Analysis

Nowadays, short-fibre reinforced composites (SFRCs) have been established for a variety of applications. However, many matrix materials, such as concrete or polymers, exhibit rate-dependent inelastic behaviour ("creep"). Since the microscopic behaviour of composites determines their macroscopic response, it is crucial to consider the complex microstructure in detail. It is possible to use the finite element method (FEM) to analyse SFRCs. Nevertheless, creating a conforming mesh for the fibres and matrix with the FEM is usually time-consuming and might also require additional constraints. In contrast, the scaled boundary finite element method (SBFEM) is ideally suited for a fast image-based discretization of microstructures because because the spatial discretization can be directly constructed by utilising the efficient quadtree-decomposition technique. Note that the SBFEM has already been successfully applied to model the elastic behaviour of SFRCs in Ref. [1]. Furthermore, it has been extended to inelastic behaviour for plasticity in Ref. [2] and rate-dependent inelasticity in Ref. [3].

The current contribution combines both approaches: First, a new non-linear constitutive model for basic creep of concrete is introduced. The model is implemented into an SBFEM framework by performing the stress update algorithm only at the scaling centre of the polytopal elements to increase the numerical efficiency. Second, creep of short-fibre reinforced concrete is modelled, whereas the new constitutive model is used for the concrete matrix. In contrast, a linear isotropic elasticity model is chosen for the fibres. The contribution at hand makes use of image-based analysis to generate meshes based on microstructural images. By means of various examples, the accuracy and efficiency of the proposed approach are numerically demonstrated.

Key Words: *scaled boundary finite element method, a quadtree mesh, nonlocal macro-micro damage model, an energetic degradation function, cracking simulation, damage*

Combined with the unified phase field theory and the concept of peridynamics, a novel nonlocal macro-micro-scale consistent damage model is proposed to simulate fracture process without prescribed initial crack and potential crack path. The model introduces the relative deformation of material point pair to describe the microscopic damage inside the structure, and then the macro-scale topologic damage is evaluated as the weighted averaging of micro-scale damage over bonds in the influence domain [1]. Since the size of the element in the damage area is small enough, it is assumed that the damage is evenly distributed in an element [2]. An energetic degradation function, which connects the energy-based damage and the macro-scale topologic damage, is introduced to consider the stiffness reduction caused by the damage, so that the topological damage can be conveniently embedded into the calculation of the global stiffness. Finally, the nonlocal macro-micro damage model is coupled into the framework of scaled boundary finite element with the scaling center as the material point. A quadtree mesh was used to refine the damage process area, and the advantage of scaled boundary finite element mesh allowing hanging nodes were fully utilized to obtain multilevel mesh effectively [3]. The model achieves efficient calculation from material point pair deformation to topological damage and reduces the computational workload and time effectively. Several numerical examples show that the proposed model can capture not only the crack pattern but also the load-deformation curves quantitatively, and model also has better computational accuracy and efficiency than the existing model. Results also indicate when the size of the element in the damage area is less than 1/5 of the radius of the influence domain, there is no mesh sensitivity in the calculated results.

Pointwise conservative SBFEM approximations based on mixed finite elements

Karolinne O. Coelho[1] **and Philippe R. B. Devloo**[2*]

[1] FEC - University of Campinas, R Josiah Willard Gibbs 85, Campinas/SP, Brazil, k192247@unicamp.dac.br

[2] FEC - University of Campinas, R Josiah Willard Gibbs 85, Campinas/SP, Brazil, phil@fec.unicamp.br

Key Words: SBFEM, Mixed FEM, $H(div)$ function spaces, Darcy Flow

In many engineering simulations, the divergence-free conditions of the approximation are perceived as an essential characteristic of the numerical method. Such conditions are common in incompressible fluid models and hard to impose using classical H^1 approximations. $H(div)$ approximations when combined with De Rham compatible L^2 approximations lead to pointwise divergence-free approximations.

The SBFEM method is known to yield convergent approximation spaces even when the geometry of the domain induces singularities, such as crack tips and re-entrant corners. The difficulty of approximating partial differential equations for such geometries is because the usual shape functions are based on polynomial interpolation functions and these lead to suboptimal converge rates. In this context, the Scaled Boundary Finite Element Method (SBFEM) emerged as an efficient and accurate strategy where only the element's skeleton is discretized, and the shape functions are defined using a semi-analytical approach [1]. The SBFEM approximations are akin to the traditional H^1 approximation and do not satisfy the divergence-free condition by construction.

In this work, we propose to extend essential ideas of SBFEM to mixed finite element approximations. The Hybridized-Mixed technique is applied to infinitesimal finite cells [2] in order to obtain the SBFEM coefficient matrices. These matrices represent the known Riccati ODE, and its solution provides the shape functions for locally conservative mixed finite elements. Thus, an SBFEM-H(div) function space is constructed to approximate the flux, and a discontinuous SBFEM space is defined for the pressure.

The mathematical formulation proposed in this study was implemented in an object-oriented FE library. Numerical tests of a Darcy flow in a 2D domain were performed and rates of convergence were computed. We also considered domains including square-root singularities, depicting the capacity of the method for simulating a flow in a fractured porous media. Optimal rates of convergence were observed, including for the flux and high-order approximations, illustrating the accuracy of the proposed approach.

Key Words: *Scaled Boundary Finite Element Method, Shell Element, Spectral Element, Assumed Natural Strain Method, Locking*

We construct within the framework of the scaled boundary finite element method [1,2] new variable-order shell elements that require only the shell midsurface to be discretized, contain no rotational degree of freedom and adopt the full three-dimensional constitutive relationship. In the formulation, a shell element is treated as a three-dimensional continuum undergoing small deformations and its middle surface is represented via a quadrilateral spectral element. The entire shell geometry is described through normal scaling of the middle surface and the displacement field across the thickness is expressed approximately by interpolating the displacements on the top, middle and bottom surfaces with quadratic Lagrange shape functions. The assumed natural strain method is applied to eliminate transverse shear locking, membrane locking and curvature thickness locking while the volumetric locking is alleviated by elevating the polynomial order. Numerical examples demonstrate that the developed shell elements are superior in applicability, accuracy and efficiency.

Resolving quasi-brittle fractures in anisotropic domains with SBFEM

Anargyros Moysidis[1*] and Savvas P. Triantafyllou[2]

National Technical University of Athens, Zographou Campus, 15780, Greece, e-mail:
[1]argimcv@central.ntua.gr, [2] savtri@mail.ntua.gr

Key Words: SBFEM, phase field, quasi-brittle fracture, anisotropy

The Scaled Boundary Finite Element Method (SBFEM) has emerged as a promising alternative to standard discretization approaches that attempts to fuse the advantageous characteristics of the Finite Element Method and Boundary Element Method onto one computational framework. Similar to the BEM, only the boundary of the domain is discretized hence reducing the dimensionality of the problem by one. The method becomes attractive especially for the case of phase field fracture simulations where fine mesh resolutions are typically required. Contrary to the BEM, no fundamental solution is required, and the overall scheme relies solely on an ansatz, as in the standard FEM. The case of brittle fracture in isotropic domains was very recently treated using SBFEM in [1].

In this work, we develop a framework for the simulation of fractures propagating in quasi-brittle anisotropic domains using the 3-parameter cohesive phase field model for anisotropic media proposed in [2]. The SBFEM is employed to discretize both the phase field and displacement based equilibrium equations of the problem. A staggered solution strategy is employed, and the solution is performed over quad-tree meshes that facilitate adaptive mesh refinement. The accuracy and efficiency of the method as compared to the standard FEM is investigated through a set of benchmarks. Furthermore, the sensitivity of the method vis-à-vis the mesh quality is examined. Our preliminary results demonstrate that the SBFEM results in robust and well behaved and accurate solutions.

Key Words: Scaled Boundary Finite Element Method, Reynolds Equation, Hydrodynamic Bearing, Cavitation, Elrod Algorithm, Rotordynamics

Hydrodynamic bearings are employed because of their high load support and damping capacity, their durability, and their compact design. However, in high-speed rotor systems, the nonlinear fluid-structure interaction can cause self-excited vibrations leading to noise emission, wear, and a reduced energy efficiency. Transient rotordynamic simulations offer a valuable tool for the prediction of this behavior but are often time-consuming, since the computation of the bearing forces requires a solution of the Reynolds equation in every time step. This equation is usually solved by means of look-up tables or numerical methods, but in both cases, a tradeoff between accuracy and computational efficiency is necessary.

In a recent study [1], a semi-analytical solution of the Reynolds equation based on the Scaled Boundary Finite Element Method (SBFEM) [2] has been developed with the objective of reducing the numerical effort of rotordynamic simulations. This solution is now extended to consider cavitation, which is a physical effect often incorporated into numerical models for improving the accuracy of the simulation. When the hydrodynamic pressure falls below a threshold, gas cavities occur inside the lubricant, changing the fluid properties and affecting the pressure generation. This effect is described by cavitation models such as the Elrod algorithm [3], which is used in this study. The corresponding SBFEM formulation of the Reynolds equation is derived, and exemplary bearing simulations are performed. It is observed that the numerical stability of the developed solution as well as the accuracy of the resulting bearing forces depend substantially on the attitude angle of the shaft relative to the position of the oil supply groove. This is due to a simplification necessary in the SBFEM model, namely that the boundary between the cavitation zone and the pressure zone has to be parallel to the scaling direction (the analytically treated coordinate direction). Possible strategies for overcoming this disadvantage are discussed in this contribution.

Key Words: *Concrete micromechanics; SBFEM; Quadtree mesh; crack propagation; stress intensity factor; cohesive interface elements.*

Abstract：The method by combining SBFEM and Quadtree mesh is developed for analyzing the interface crack problems of double material plate. The distributions of generalized stress intensity factors can be obtained around crack tip within 360 degrees. According to the distribution rules of the generalized stress intensity factors, the cracking criterion with considering the comprehensive effect of K is proposed. The influence of the size of the crack tip element on the singular order is discussed and the reasonable size of crack tip element for fracture analysis is proposed. Nonlinear cohesive interface elements with normal and shear traction-separation constitutive laws are considered in the cracking process. The effect of hydraulic fracturing on the concrete cracking and propagation at mesoscale is discussed. The methods combining SBFEM and Quadtree mesh are used for numerical analysis of concrete specimens at mesoscale with considering the interaction between the water pressure along crack surface and the crack propagation. The finite volume method is used to establish the coupling model of water pressure along crack surface and crack width. The water pressure distribution along crack surface is solved iteratively. The modelled crack paths and load-carrying capacities of concrete specimens are in excellent agreement with the experimental data.

Spatially Variable Coal Slope Stability Analysis using Image-Based Scaled Boundary Finite Element Method

Key Words: *Slope stability, SBFEM, spatial variation, image-based meshing*

Slope stability analysis is a challenging task when complex stratigraphies, complex geometries and spatially variably soil parameters are considered. Numerical methods, such as the finite element method are commonly used in slope stability analyses, however these methods require significant user input when meshing geometries consisting of heterogeneous and spatially variable materials. This paper presents a numerical technique combining the scaled boundary finite element method and image-based meshing for slope stability analysis. The inputs for the analyses require images detailing the strata and the spatial variation of the material properties within the strata. Quadtree decomposition was applied to simultaneously generate meshes and consider the spatial variation of material properties directly from the images through a mapping technique. The stability of slopes were analysed assuming an elasto-plastic Mohr-Coulomb constitutive model for the soil. The shear strength reduction technique is applied to evaluate the shear reduction factor iteratively to define the factor of safety of the stable slope. Coal slope at Yallourn open-pit mine,Victorial, Australia was used as a case study to demonstrate the application of the presented method.

Three-dimensional Non-linear Numerical Analysis of Randomly Distributed Short Fiber-Reinforced Composites using the Scaled Boundary Finite Element Method

Shukai Ya[1*], Sascha Eisenträger[1] and Chongmin Song[1]

[1] University of New South Wales, Sydney, NSW 2052, Australia, s.ya@unsw.edu.au

Key Words: *Scale boundary finite element method, Short fiber-reinforced composite, Non-linearity, Discrete modelling, Fiber/matrix debonding*

This contribution presents the three-dimensional numerical modelling of randomly distributed short fiber-reinforced composites (SFRCs) with the scaled boundary finite element method (SBFEM)[1]. Automatic mesh generation of SFRCs in a discrete fashion is utilized to generate conforming meshes of the matrix and the fibers[2, 3]. To this end, three phase non-linear materials including matrix, fiber and interface are incorporated, which allows to simulate the progressive failure of SFRCs considering matrix cracking, fiber breakage and fiber/matrix debonding simultaneously. The analyses are performed on the platform ABAQUS through polyhedral user elements (UEL) derived by the SBFEM[4]. Damage constitutive law is employed to simulate the non-linear behaviour of matrix. The fiber and interface are represented by beam and spring elements with inelastic mechanical properties, respectively. The proposed model provides a relatively realistic simulation of randomly distributed SFRCs which considers complex microstructures with less demanding of computational resources and human efforts on meshing. The accuracy, robustness and efficiency of the proposed approach are demonstrated by means of serval numerical examples.

Key Words: Scaled Boundary Finite Element Method, Wave Propagation, Unbounded Domain, Explicit Dynamics

To solve wave propagation problems in soil or soil-structure domains using standard finite elements, very large domains must be modeled to avoid reflections at the artificial boundaries or to increase the accuracy of absorbing boundary conditions. Especially for three-dimensional problems, this procedure can become very costly and inefficient.

An alternative approach is to use the scaled boundary finite element method (SBFEM) and to define an unbounded subdomain, which is described by scaling the soil-structure interface towards infinity. Here, the reaction forces at this interface are calculated by using the acceleration unit-impulse response method. As a result, a convolution integral is present in the equations of motion of the bounded domain. In existing publications, these are solved using implicit time-stepping schemes, such as Newmark's method [1].

In this contribution, an explicit time integration scheme for acceleration unit-impulse response-based models of unbounded soil-structure systems is proposed. The motivation is that various techniques for increasing the efficiency of bounded domain models, such as mass lumping [2] or exploiting similarity of structured meshes together with parallel computing [3], are tailored to explicit solvers. This can be exploited especially in large three-dimensional models and reduce computation time. Both strategies, implicit and explicit methods, are compared and discussed with respect to benefits and disadvantages in the context of transient soil-structure interaction modeling.

Key Words: VEM, phase field, ductile fracture, cohesive surfaces, particulate composites

Particulate composites are widely used in the aerospace, automotive, and construction industry to improve the mechanical performance of structural components. Additive manufacturing paved the way for generating tailor made multi-material layouts of optimal properties; unfortunately, optimum additively manufactured domains often involve tessellated geometries. This gives rise to complex and involved damage patterns that need to be accurately estimated at the design phase. This necessitates the use of numerical methods, e.g. the FEM to resolve damage patterns. However, when the domain comprises arbitrarily shaped inclusions the efficiency of the solution procedure is hindered by the mesh refinement restrictions imposed by the domain topology.

Polygonal element topologies have been shown to provide flexibility to overcome such issues.The Virtual Element Method [1] emerged from Mimetic Finite Differences (MFDs) as an accurate and efficient alternative to FEM, designed to address this issue. Shape functions are implicitly defined through carefully chosen degrees of freedom. State matrices are computed through projection maps without affecting optimal error convergence rates. In this work, we explore the potential of the VEM to efficiently resolve ductile fractures in particulate composites within a small strain setting. Driven by the work of [2] we develop a ductile fracture phase field model within a VEM setting and combine it with a cohesive surface approach to account for de-bonding at the matrix to inclusion interface. Further to the current state-of-the-art, the case of J2 and Druger-Prager plasticity is examined, accounting for metal and ceramic matrix composites, respectively.

Our preliminary results demonstrate that the VEM results in robust solutions that are more computationally efficient when compared to the standard FEM while achieving in resolving fractures in matrices containing arbitrary shaped inclusions when compared to the standard Finite Element Method.

Key Words: *Virtual element method, adaptive mesh refinement*

The virtual element method (VEM) is an extension of the finite element method that permits arbitrary polygonal element geometry in two dimensions [1]. This mesh flexibility means that the VEM is well-suited to problems involving adaptive mesh refinement. However, the virtual element function spaces are defined such that quantities are only explicitly known on element edges. Thus, the well-known approaches to mesh adaptivity developed for finite elements cannot be directly applied to problems involving the VEM.

A variety of approaches to adaptive mesh refinement procedures have been formulated and implemented for the VEM for the case of two-dimensional elastic problems. The approaches are motivated by seeking to improve the approximations of the displacement and/or strain fields. The performance of these approaches has been investigated in terms of accuracy vs computational cost compared to a traditional reference mesh refinement procedure.
The performance was studied through a range of numerical benchmark problems, including the well-known L-shaped domain and punch problems.

The the results demonstrate that each of the adaptive mesh refinement procedures consistently generates solutions of equivalent accuracy to the reference procedure while using significantly fewer degrees of freedom, and significantly less run time, representing a dramatic improvement in computational efficiency and improved convergence behaviour [2].

Key Words: Polytopal meshes, Virtual Element Method, Adaptivity

Virtual element method (VEM) is a relatively new discretization paradigm which allows the numerical solution of partial differential equations on general polytopal meshes. This geometric flexibility is very useful in many solid and fluid mechanics applications, in particular when adaptive mesh refinement is employed on moving or very complicated geometries. In this talk, we present recent advancements in the understanding and practice of the adaptive virtual element method (AVEM) for the solution of partial differential equations. In particular, we will discuss through extensive numerical experiments both practical and theoretical issues, ranging from the strategy of refining a general polytopal to the study of the convergence and computational complexity of the adaptive algorithm based on the iteration of the classical paradigm:

$$\texttt{ESTIMATE} \rightarrow \texttt{MARK} \rightarrow \texttt{REFINE} \rightarrow \texttt{SOLVE}$$

where the module `ESTIMATE` computes a posteriori error estimators, `MARK` identifies the polytopal elements to be refined, `REFINE` performs the refinement of the marked elements and `SOLVE` finds the discrete approximation on the adaptively refined mesh.

First-Order Virtual Elements for the Shear Deformable Plate Problem

Key Words: *Reissner-Mindlin plates, Virtual Element Method, Locking-free, Polygonal meshes*

In this contribution, the construction of first-order virtual elements for the shear deformable plate problem is presented and discussed. Transverse displacement and rotations are assumed as independent variables, in the framework of a standard displacement-based variational formulation. A piecewise linear approximation is adopted on the boundary of the polygonal element for both transverse displacement and rotations.

Uncoupled polynomial approximations for the generalized strains, with different polynomial degrees for the bending and shear parts, are assumed for the construction of the consistent term of the stiffness matrix.

With the aim of preventing shear locking in the thin-plate limit and keeping the construction of the element as simple as possible, an indirect enrichment of the approximation of the transverse displacement with respect to that of the rotations is introduced through a selective scheme for the stabilization term of the stiffness matrix [1].

The performance of the method is tested through several numerical examples involving thin and thick plates and by using different polygonal meshes. As a result, the proposed first-order virtual elements allow to save degrees of freedom with respect to existing approaches [2,3] while keeping comparable results.

Key Words: *Virtual Element Method, Cohesive Fracture, Element Split, Stress Recovery*

This study presents a computational framework for mixed-mode cohesive fracture simulation using the virtual element method (VEM). Because VEM is able to consistently handle arbitrary shped elements [1], VEM is one of the best candidates for the crack path representation in cohesive fracture simulation. To represent an arbitrary and curved crack path on polygonal discretization, the element splitting approach is employed [2,3]. For the accurate approximation of a crack-tip stress field and the crack propagation direction, the virtual grid-based stress recovery scheme (VGSR) [3,4] is utilized with the maximum strain energy release rate. To verify and validate the accuracy and robustness of the proposed computational framework, the mixed-mode fracture examples are illustrated. Numerical results demonstrate that VGSR-based crack growth criterion well captures an accurate crack path direction, even under the biaxial stress state. In addition, the computed crack patterns using the element splitting process show that smooth and curved cracks on polygonal elements, and good agreement with the experimental results.

Key Words: Virtual element method, Nonlinear plates, Γ-convergence, Discrete gradient flow

In this presentation, we introduce an ongoing work about a virtual element method (VEM) for approximating large deformations of plates with isometry constraints. We study both single layer plates and bilayer plates in this project, and for latter we consider both Dirichlet boundary conditions and free boundary conditions. The problem consists of minimizing a bending energy subject to a nonlinear and nonconvex constraint. The energy is discretized using VEM and a discrete gradient flow is designed for computing discrete minimizers. We first show Γ-convergence of the discrete energy to the continuous one. Then we prove that the discrete gradient flow decreases the energy at each step and computes discrete minimizers with control of the isometry constraint defect in L^∞ norm. We also illustrate the performance of our algorithm with several insightful simulations.

Contrary to previous finite element methods (FEM) for this type of problem, which use Kirchhoff elements [1], discontinuous Galerkin (DG) methods [2] and local discontinuous Galerkin (LDG) methods [3], this VEM method can formally allow arbitrary order of discretization, and this is a main advantage of the our method. A key ingredient in the analysis is an inverse inequality for L^∞ norm of functions in a virtual element space. Moreover, in the method for bilayer plates, we also propose a novel enhanced virtual element space and interpolation operator, which turns out to be crucial in the treatment of the nonlinear term appearing in the energy for bilayer plates.

Key Words: *Finite volume method, High-order and shock-capturing scheme, BVD principle*

Boundary Variation Diminishing (BVD) schemes [1] have been recently developed as a high-fidelity Godunov-type finite-volume method for compressible flows. In general, it is necessary to reduce numerical dissipation of the numerical schemes in order to resolve wide-range scales of flow structures. The numerical dissipation can be effectively reduced by the BVD principle [1] that diminishes the difference between the left- and right-value of a reconstructed physical quantity at the cell boundary. Following this principle, the BVD scheme was extended to combine the existing high-order scheme with the THINC (Tangent of Hyperbola for INterface Capturing) scheme [2] that is suitable for capturing the discontinuities. Such hybrid-type schemes can resolve both smooth and discontinuous solutions with high resolution.

To explore further possibility of the BVD schemes, we investigate the effectiveness of β-variable THINC scheme [3], in which the steepness parameter β of the THINC function is changed locally. The algorithm to calculate the appropriate value of β for each cell is developed and the β-variable THINC scheme is embedded into the existing BVD formulation. The new BVD scheme can resolve the small vortices more clearly by adapting the value of β based on the local solution and simultaneously suppress the computational cost by reducing the number of candidate reconstruction functions.

Furthermore, the BVD principle can be applied to the calculations of the compressible multi-phase flows including moving interfaces as in cavitation and atomization. In such flows, the shape of the gas-liquid interface may change drastically. Therefore, it is more important than in the case of single-phase flows to suppress the numerical dissipation and capture the discontinuous solutions with high resolution. The effectiveness of the BVD scheme will be assessed by the benchmark tests relevant to actual problems (primary breakup of liquid jet inside rocket engine combustors, etc.).

Efficient approaches to CFD simulations of reactive flow using reliable chemical reaction models

Youhi Morii[1*], Kaoru Maruta[2]

[1] Institute of Fluid Science, Tohoku University, 2-1-1 Katahira, morii@tohoku.ac.jp
[2] Institute of Fluid Science, Tohoku University, 2-1-1 Katahira, maruta@ifs.tohoku.ac.jp

Key Words: *Combustion, Chemical Reaction, Stiffness*

Combustion has been applied as an energy source in various fields, but its detailed phenomena are still unknown due to the complex interaction of fluid dynamics and chemical reactions. Therefore, it is desirable to reproduce combustion phenomena by CFD simulation. However, the scale of a practical combustor is much larger than that of a flame and solving chemical reactions with an increasing number of strongly nonlinear equations to be solved dramatically increases the computational cost. For this reason, CFD simulations of combustion often solve chemical reactions in a greatly simplified manner, which does not lead to a detailed understanding of combustion phenomena. In addition, there is a recent need to reduce CO_2 emissions. Therefore, there is a rapid demand for the development of combustors that can operate near the combustion limit to achieve higher efficiency and the use of biofuels and synthetic fuels, and it is becoming difficult to deal with this issue using conventional CFD simulations that cannot handle chemical reactions accurately.

The main computational cost is due to the chemical reactions, for which implicit methods are generally applied due to their stiffness. As a result, the computational cost of generating the Jacobi matrix used in implicit methods is the square or cube of the number of chemical species. In the case of hydrocarbon fuels, the number of chemical species ranges from hundreds to thousands, making the computational cost impractical. Accordingly, Morii et al. have developed robust integration methods that do not require the Jacobi matrix [1, 2]. With the development of these methods, the computational cost is only proportional to the number of chemical species, and the computational cost has been significantly reduced. To further reduce computational cost, the developed methods have been incorporated into PeleC software [3], which incorporates AMReX, a library of adaptive mesh refinement methods. As a result, direct numerical simulations on an experimental scale are now possible and the results can be compared quantitatively with respect to knocking [4], which has been a problem in improving the efficiency of SI engines. However, in order to apply CFD simulation to the development of actual engines, further reduction of the computational cost is required.

GPU Accelerated Paired Explicit Runge-Kutta Schemes in HORUS

Brian C. Vermeire[1]*

[1] Concordia University, 1455 De Maisonneuve Blvd. W, Montreal, QC, Canada, H3G 1M8,
brian.vermeire@concordia.ca

Key Words: GPU, accelerated, high-order, paried explicit Runge-Kutta, speedup

Scale resolving simulations, such as Large Eddy Simulation (LES) and Direct Numerical Simulation (DNS), require accurate, efficient, and stable discretizations of the Navier-Stokes equations. Recent research has demonstrated that high-order spatial discretizations, such as the Flux Reconstruction (FR) approach, are particularly appealing when coupled with explicit Runge-Kutta (RK) schemes on Graphical Processing Units (GPUs). This has been shown to be an order of magnitude faster and, simultaneously, an order of magnitude more accurate than industry standard Finite Volume (FV) methods [1]. However, one disadvantage is that high-order schemes have increased numerical stiffness. This limits the maximum allowable time step size, and prohibits their use beyond Reynolds numbers of approximately $Re \leq 10^6$.

Paired Explicit RK (P-ERK) schemes have been proposed as a solution to this problem [2]. Families of P-ERK schemes have an arbitrary number of stages, and each member of a family has a different number of *active stages*. Members with more active stages require more unsteady residual calculations, yielding larger stability limits. Members with fewer active stages require fewer unsteady residual calculations, but have lower computational cost. All members from the same family can be paired seamlessly, allowing schemes with more active stages to be used in stiff regions, wheras schemes with few active stages are used in non-stiff regions. Previously, it has been demonstrated that P-ERK schemes yield 5-10x speedup relative to classical explicit RK methods on Central Processing Units (CPUs).

In this work we will demonstrate the utility of P-ERK schemes combined with GPU acceleration in the High-ORder Unstructured Solver (HORUS) developed at Concordia University. Using this approach HORUS can obtain speedup factors in excess of 30-50x on a per-node basis when compared to classical RK schemes on CPUs. This is observed over a range of different simulations including turbulent flow over a sphere, tandem spheres, and a stalled airfoil. In this talk we will discuss implementation details of P-ERK schemes on GPUs, partitioning, scaling, and show results for a range of different practical LES/DNS simulations. Finally, recommendations will be made for the use of P-ERK schemes combined with high-order methods for high Reynolds number flows.

Hybridized Flux Reconstruction Methods for Convection-Diffusion Problems

Carlos A. Pereira[1*] **and Brian C. Vermeire**[1]

[1] Concordia University, Montreal, Quebec, Canada

Key Words: Flux Reconstruction, Implicit Discretizations, Hybridization, Convection-Diffusion problems

High-order methods have become a promising approach for the analysis and optimization of problems involving complex fluid flows. In particular, the flux reconstruction (FR) method of Huynh [2] has been shown to be an attractive choice amongst a variety of existing schemes [3]. The FR approach is able to recover existing high-order discretizations and define new methods via the choice of correction functions [2, 4].

Often, high-order methods are used in conjunction with explicit time-stepping due to their simplicity. However, for stiff problems, the maximum allowable time-step size can be prohibitively small. On the other hand, implicit time-stepping is also prohibitively expensive due to a large number of degrees of freedom in the resulting systems of equations. These scale as p^{2d} where d denotes the number of dimensions.

In this work, we propose a new implicit flux reconstruction framework for convection-diffusion problems. These methods apply the hybridizable high-order discontinuous Galerkin approach of Cockburn et al. [1] to the family of FR schemes. This hybridization allows for a reduction of the scaling of the implicit system size to that of an effective lower dimension. This is possible by introducing unknowns on the skeleton of the grid as well as an additional global conservation statement. Hence, the problem can be rewritten in terms of this trace unknown using static condensation.

We will show how hybridized FR methods can significantly reduce the computational cost of convection-diffusion implicit problems, particularly for higher-order discretizations. Furthermore, we present a new elementwise postprocessing scheme in which we use FR correction functions to improve flux convergence and thus obtain solutions that are more accurate and have better convergence rates. These findings are supported by verification and validation studies on a series of numerical examples.

INVESTIGATION ON GRID RESOLUTION REQUIREMENTS FOR HIGH-ORDER IMPLICIT LARGE EDDY SIMULATION

Juhyun Kim[1*], Hojun You[2], and Chongam Kim[3]

[1] Seoul National University, Seoul 08826, Republic of Korea, kjhunkk@gmail.com
[2] Seoul National University, Seoul 08826, Republic of Korea, rememory@snu.ac.kr
[3] Seoul National University, Seoul 08826, Republic of Korea, chongam@snu.ac.kr

Key Words: Optimal Grid Resolution, Implicit Large-Eddy Simulation, Discontinuous Galerkin Method, High-order Method, Turbulent Flow, Kriging Meta-model

This research aims to find a baseline grid configuration that provides cost-efficient and accurate solutions for high-order implicit large-eddy simulation (ILES). To achieve this, the optimal grid resolution for high-order ILES is estimated using the Kriging meta-model. Based on the Kriging optimization, approximated relational expressions between the solution approximation order and the optimal grid configuration, named the grid-$\mathbb{P}^k$ relations, are proposed in order to provide a guideline of a proper grid resolution for ILES using high-order methods.

A fully developed turbulent channel flow at $\mathrm{Re}_\tau = 180$ is employed as a model problem to elicit the optimal grid resolution. Every computation is conducted using a high-order accurate solver based on the modal Discontinuous Galerkin method [1]. Turbulent statistics are collected from the turbulent channel flow simulation on a series of grid configurations (i.e., minimum wall-normal grid spacing, stretch ratio, and spanwise grid spacing). An objective function is defined as the L_2 error of the streamwise mean velocity, and a cost constraint is imposed to avoid a trivial conclusion. Through the optimization process by the Kriging meta-model and genetic algorithm, a set of optimal grid resolutions for various solution approximation orders (*P2*, *P3*, and *P4*) are obtained.

From the optimization results, the grid-$\mathbb{P}^k$ relations estimating the optimal grid resolution for high-order ILES are proposed. Those are validated by turbulent channel flows at $\mathrm{Re}_\tau = 180$, $\mathrm{Re}_\tau = 395$, and $\mathrm{Re}_\tau = 550$ and external transitional flows over an SD7003 airfoil at $\mathrm{Re} = 60,000$. The ILES results of turbulent channel flows are compared to DNS results, and the flow over the SD7003 airfoil is compared to other high-fidelity computations. As a result, the computations of both internal and external flows match well with the reference solutions so that support the validity of the proposed grid-$\mathbb{P}^k$ relation.

Key Words: *Flux Reconstruction, Supercritical Jet, Non-premixed Flame, LES*

Modern high performance liquid rocket engines (LREs) operate at very high combustion pressures over 10 MPa with propellant injection at cryogenic temperatures. Under such trans-critical conditions, the real-gas effect of propellants must be considered to predict liquidlike dense fluid behaviour and nonideality of thermodynamic properties [1]. The large and abrupt change of thermodynamic properties across the contact discontinuity between cryogenic propellants and hot combustion gas make robust and accurate simulations difficult. In particular, the high-order schemes required for accurate large-eddy simulations (LES) are more likely to suffer from numerical instability.

In this study, the high-order flux reconstruction (FR) method [2] is developed for liquid oxygen (LOX) and gaseous hydrogen (GH2) coaxial jet flames under supercritical pressures. The SRK equation of state is used to account for real-gas effect and the Chung's transport coefficient model is employed for LOX. To overcome the numerical instability for the conservative FR formulation, the invariant region preserving (IRP) limiter [3] is extended for the real-gas mixture. First, two-dimensional LOX/GH2 inert turbulent mixing layer is computed for verifying the performance of the proposed scheme. Then, LES of the turbulent diffusion flame of single coaxial LOX/GH2 injector is performed using the flamelet progress-variable (FPV) tabulated approach [4]. A high-performance computing application of the full-scale engine combustor LES with more than 500 injectors will be presented.

Key Words: *Entropy stable flux reconstruction, Large-eddy simulation*

High-order numerical methods, such as Discontinuous Galerkin (DG) and Flux Reconstruction (FR), i.e. FR-type methods, are particularly appealing for the Large Eddy Simulation (LES) of turbulent flows, as they show significant potential to improve simulation accuracy at comparable or reduced computational cost [1]. In LES, the unsteady turbulent motion is decomposed into a filtered (resolved) component, representing large-scale energy containing eddies, and a residual component by use of a low-pass filter. Due to the convenient spectral dissipation properties of FR-type methods, this filtering can be performed implicitly by the numerical dissipation of the spatial discretization scheme; this is referred to as implicit LES (ILES). Furthermore, in LES, the effect of the residual motions on the resolved scales is modelled by a sub-grid scale (SGS) model, representing a residual-stress tensor; which effectively dissipates turbulent kinetic energy (TKE) from the smallest resolved scales. In general, the truncation error of FR-type schemes resembles an additional numerical stress and amounts to an implicit SGS model, having similar influence as conventional SGS models; this is referred to as no-model ILES. However, despite the success of FR-type methods for the no-model ILES of turbulent flows at moderate Reynolds number flows, their application to industrially relevant simulations, consisting of higher Reynolds number flows or requiring coarser grids, has been limited ultimately due to the absence of nonlinear stability. It has recently been demonstrated that these limitations can be overcome with the use of energy stable DG schemes for ILES, possessing superior robustness and the ability to strongly increase fidelity on very coarse grids [2]. These promising results encourage the development of provably nonlinearly stable FR schemes for ILES, given the advantages of FR over DG such as larger explicit time stepping. Recently, the first critical step towards this has been taken with the newly proposed framework of generalized provably nonlinearly stable FR schemes in split form that enable both energy/entropy stability and conservation proofs, referred to as Entropy Stable Flux Reconstruction (ESFR) [3]. In this work, we present a novel ILES approach based on adaptive nonlinearly stable ESFR schemes (ESFR-ILES) that is well suited for shock-free turbulent flows by extending the original work on ESFR schemes to 3D systems of conservation laws. The use of the ESFR schemes for the ILES of shock-free turbulent flows is investigated and its performance with the use of various SGS models is demonstrated for both the viscous Taylor-Green Vortex (TGV) problem, and a decaying homogeneous isotropic turbulence (DHIT) test case.

[3] Imperial College London, London SW7 2AZ, UK, p.vincent@imperial.ac.uk

Key Words: Martian Aerodynamics, Optimization, Direct Numerical Simulations, Low-Reynolds-Number

Martian atmospheric conditions present various challenges when designing rotorcraft. Specifically, Mars has a thin atmosphere with lower pressure and density compared to Earth, reducing the performance of conventional airfoils. Additionally, the speed of sound on Mars is approximately 72% of that on Earth which constrains rotor speeds in order to avoid high Mach numbers at rotor blade tips. These unique conditions require Martian rotor blades to operate in a low-Reynolds-number ($\approx 10^3$ to 10^4) compressible flow regime, for which conventional airfoils have not been designed.

Recent studeis have investigated the perfromacne of non-conventional airfoil designs, with sharp edges and flat surfaces, under Martian atmospheric conditions [1] [2]. Further studies have explored optimizing such airfoils using Genetic Algorithms (GAs) [2]. These involve a high number of cost function evaluations, and hence typically Reynolds-Averaged Navier Stokes (RANS) solvers are employed to bound overall cost. However, RANS solvers have reduced predictive capability when the flow becomes unsteady at moderate angles of attack, thus limiting the utility of the approach. Our work looks to overcome this limitation by undertaking optimization using high-order Direct Numerical Simulations (DNS) using PyFR (www.pyfr.org) [3].

In this talk, we will present results from GA based multi-objective optimizations of non-conventional airfoils at various angles of attack under Martian atmospheric conditions. The findings can be used to help design new rotorblades for next-generation Martian rotorcraft.

PyFR is a high-order accurate Computational Fluid Dynamics (CFD) solver based on the Flux Reconstruction approach of Huynh [1]. It is written in Python, and can target a range of hardware platforms via an innovative Mako-based domain specific language [2]. Over the past decade PyFR has matured into an established part of the open source CFD ecosystem. It now has an active community of users around the world, and is routinely applied to undertake high-fidelity scale-resolving simulations across a range of application areas, including at extreme scale. This talk will present results from some of the latest simulations to be undertaken with PyFR, and provide insight into some of our latest technological developments, including cache blocking optimisations for the CPU backend, turbulence injection approaches, and new shock capturing methods. Finally, we will outline our roadmap for future development of the solver.

Key Words: *Runge-Kutta methods, Optimal time-stepping, Flux reconstructions*

In this paper, we expand the family of Paired Explicit Runge-Kutta methods, referred to as P-ERK schemes, to third-order accuracy in time. The P-ERK approach is particularly appealing for the solution of locally stiff systems of Partial Differential Equations (PDEs) to reduce computational cost. Previously, it was shown that P-ERK family members with different numbers of derivative evaluations can be applied to different regions of the domain, based on local stiffness requirements, so the global time-step to be taken as large as possible [1]. However, the original family of P-ERK schemes is limited to second-order accuracy [1]. In this study, we introduce a new family of P-ERK methods with third-order accuracy, and optimize them specifically for high-order flux reconstruction [2] spatial discretizations [3]. We verify that these methods achieve their designed order of accuracy for an isentropic vortex case with arbitrary combinations of schemes. We then demonstrate that simulations with the third-order P-ERK family can achieve significant speedup factors compared with classical third-order Runge-Kutta methods. These speedup factors are obtained for laminar and turbulent flow over an SD7003 airfoil and a turbulent tandem spheres simulations. These results demonstrate the P-ERK schemes are a suitable approach for accelerating high-order accurate simulations of unsteady turbulent flows.

Utilizing Time-Reversibility for Shock Capturing in Nonlinear Hyperbolic Conservation Laws

Tarik Dzanic[1*], Will Trojak[1] and Freddie Witherden[1]

[1] Texas A&M University, College Station, TX 77843, (tdzanic/wt247/fdw@tamu.edu)

Key Words: *Shock capturing, artificial viscosity, hyperbolic systems*

The approximation of systems of nonlinear hyperbolic conservation laws remains a challenge for the development of many high-resolution numerical schemes due to their lack of robustness in the vicinity of discontinuities. For these systems, discontinuities can, and often do, arise from initially-smooth data, and without proper treatment, can result in spurious oscillations that can degrade the quality of the solution or cause the scheme to fail altogether. Various nonlinear stabilization techniques have emerged among practitioners of high-order numerical schemes, and these techniques share a common goal of robustly resolving discontinuous features while recovering high-order accuracy in smooth regions. The addition of an artificial viscosity can be considered to be the most ubiquitous stabilization method for numerical schemes. This approach possesses several favorable properties in that it can robustly resolve discontinuities, is simple to implement and extend to unstructured grids, and has rigorous mathematical backing in the context of hyperbolic conservation laws. However, determining where and how much artificial dissipation to apply is an open problem, as the stability of the scheme can suffer if not enough dissipation is introduced in the vicinity of a shock, but solution accuracy in smooth regions can be severely degraded if unnecessary dissipation is applied.

In this talk, we will describe a novel approach for estimating the artificial dissipation required for robustly resolving discontinuous features in hyperbolic conservation laws. The artificial viscosity term is calculated based on an estimation of the reversibility of the system, utilizing the fact that entropy production by shocks imposes a time-irreversibility condition on the solution. The proposed approach can be applied without any additional governing equations, is independent of the mesh and approximation order, does not require a priori knowledge of the hyperbolic system in question, and requires the use of only one tunable parameter. The primary novelty of this method is that the resulting artificial viscosity is unique for each component of the conservation law which can significantly improve the accuracy of the approximation of systems in which some components exhibit discontinuities while others do not without additional computational cost. The efficacy of this method will be shown through numerical simulations in the context of a high-order discontinuous spectral element method for hyperbolic conservation laws such as the Euler equations and ideal magnetohydrodynamics.

Key Words: Unfitted, Cut-cell, Immersed, Sharp interface, High-order, Discontinuous Galerkin

A wide range of multiphysics problems arising from different scientific fields are dominated by multi-material interactions. When complex interface geometries are at stake, the applicability of established boundary or interface mesh-conforming discretization may be strongly limited, especially for moving interface problems. Past and current intense developments of geometrically unfitted methods have opened the way to new simulations capabilities. Among this broad family of methods, the so-called eXtended Discontinuous Galerkin (XDG) Method introduced in [1] and further developed in our previous work [2, 3] is the focus of the present paper.

While highly increasing versatility, decoupling the finite element approximation space from the background mesh entails additional difficulties for the XDG method that will be addressed in this work: (i) interface representation and motion, (ii) management of independent sets of degrees of freedom in cut-cells, (iii) integration over implicitly defined domains, (iv) treatment of small cut-cells, (v) time-integration on moving domains, (vi) interface coupling conditions enforcement.

The presentation will cover the aspects described above accompanied by illustrative test cases. Particular emphasis will be placed on the novel proposed coupling strategy for complex multi-material problems, such as viscous compressible gas-liquid flows.

A higher-order fictitious domain method for structural membranes and shells

Thomas-Peter Fries [1]

[1] Institute of Structural Analysis, Graz University of Technology,
Lessingsstr. 25, 8010 Graz, Austria, www.ifb.tugraz.at
fries@tugraz.at

Key Words: *Membranes, Shells, Cut FEM, Trace FEM, fictitious domain method, PDEs on manifolds.*

Structural membranes and shells are modelled by partial differential equations posed over curved two-dimensional surfaces in the three-dimensional space. Herein, these surfaces are embedded in a three-dimensional background mesh composed by higher-order elements and a fictitious domain method (FDM) is proposed for the approximation. Such a method may also be labelled Cut FEM or Trace FEM [3,4]. The governing equations of structural membranes featuring large displacements as well as linear Kirchhoff-Love and Reissner-Mindlin shells are formulated based on the Tangential Differential Calculus (TDC) [1-3]. The geometries of the structures are implied by the level-set method, prescribed at the nodes of the higher-order background mesh and interpolated in-between.

In any FDM, the following three issues have to be addressed: (1) The numerical integration of the weak form in the (three-dimensional) background elements which are cut by the membrane or shell. Therefore, the zero-level sets of the level-set functions have to be identified and integration points defined. (2) The application of boundary conditions within the background elements which is done based on Nitsche's method here. (3) The stabilization with respect to shape functions with extremely small supports on the structure. When using FDMs for the approximation of PDEs on manifolds, a stabilization is also required to tackle linear dependencies of the three-dimensional shape functions of the background mesh when applied to the analysis of the (curved) two-dimensional structures. Numerical results show the success of the proposed formulation.

Key Words: Geophysics, Parametric problems, Inverse problem, Poisson problem, Interface

Inverse problems in geophysics seeking to understand the current state of planet Earth use data from multiple observables and involve a variety of physical principles. One of the key fields to determine is the temperature, and it affects almost all the other physical quantities involved (e.g. densities, viscosities, wave propagation velocities, among others).

Within inverse problems, the parameters determining the interface locations are usually to be determined. Some of these interfaces are defined by isotherms. The inverse solver requires the solution of many forward problems where the location of the interface change. Consequently, the isotherm position in the computational domain changes. Setting Dirichlet conditions within the domain might lead to ill-posed problems.

In this work, we will analyse the one, two and three-dimensional cases in a simple setup to understand the issue and propose a well-posed problem statement and a numerical solution strategy.

A Posteriori Error Control and Adaptivity for the Finite Cell Method

Paolo Di Stolfo[1] **and Andreas Schröder**[2*]

[1] Department of Mathematics, University of Salzburg, 5020 Salzburg, Austria,
paolo.distolfo@plus.ac.at
[2] Department of Mathematics, University of Salzburg, 5020 Salzburg, Austria,
andreas.schroeder@plus.ac.at

Key Words: finite cell method, a posteriori error control, adaptivity

The finite cell method is an immersed boundary method which combines a fictitious domain method with a (higher-order) finite element method [1]. Its basic idea is to replace the possibly complicated physical domain by an embedding domain of a geometrically simple shape which can easily be meshed. The variational formulation of the problem and its finite element discretization is defined on the embedding domain. The geometry of the physical domain is incorporated via an indicator function, which necessitates the implementation of an appropriate quadrature scheme.

The talk presents concepts of a posteriori error control for the finite cell method. The focus is on a residual-based error control for the reliable estimation of the discretization error with respect to the energy norm [2] and on the application of the dual weighted residual approach (DWR), which enables the control of the error in terms of a user-defined quantity of interest [3, 4]. In particular, the use of the DWR approach allows for the separation of the discretization error and the quadrature error. Both concepts of error control can be used to steer adaptive schemes for local mesh refinements. In several numerical experiments the performance of the error controls and the adaptive schemes is demonstrated.

Key Words: *Moment fitting, Neural network, Weak discontinuity, Enrichment strategy*

As it removes the computationally expensive operation of generating the body-fitted mesh, the enrichment technique has been widely employed to consider structural discontinuities within an element. The standard shape function is locally hybridized with an enrichment function, enabling either state variable (e.g., displacement) or its derivative fields to contain discontinuity within the function. Irregularities such as jump, kinks, and other non-smoothness of a displacement field or its gradients are approximated, and the accuracy of the solution increases accordingly. The remarkable success of the techniques is based on the robustness and generality of the method, which is underpinned by the fact that the enriched function retains partition of unity properties. However, the enrichment techniques typically introduce a challenge in domain integration since the Gauss quadrature, which assumes Gauss-Legendre polynomial as an integrand, cannot be used in the standard form. Such changes, furthermore, often incur a high computational cost that is in proportion to the number of enriched elements, which is tied to the accuracy of the solution. For instance, in the extended finite element method (XFEM) [1], one of the most widely used enrichment methods, the number of Gauss quadrature points increases rapidly in proportion to the number of enriched elements.

This work introduces a novel method that calculates quadrature weights that adaptively change depending on discontinuity geometry. Inspired by a novel adaptive quadrature method presented recently [2], which reduces the computational load by fixing the number of integration points regardless of the discontinuity, we also combine the moment fitting method and the selective enrichment strategy. Additionally, we present a way to further accelerate computing the weights by leveraging the potential of the artificial neural network, a standard machine learning technique. Thanks to the nonlinear regression provided by the trained network [3], the computational overhead is minimized without sacrificing the accuracy of the solution: time-consuming operations- the calculation of the moments and the model's training-are done in the offline stage. Furthermore, we improve the solution accuracy without increasing the finite element grid by adjusting the moments by a detailed representation of the enrichment. We demonstrate the accuracy and efficiency of the proposed method by solving several numerical examples.

Key Words: Bone Remodelling, Image-Based Finite Element Analysis, Biological Factors

The development of tailor-made medical applications, such as personalised prosthetic implants benefits from the accurate prediction of short and long term bone remodelling simulation. The present work describes a numerical technique to reduce modelling errors through the derivation of patient-specific biological factors and physiological actions affecting this processes.

In the literature, the simulation of bone remodelling usually involves coarse estimations in the imposed physiological structural boundary conditions and the biological parameters included in the formulation of the remodelling algorithms. These generic assumptions, which introduce a large amount of modelling errors, are applied since the actual measurement of the modelling environment in each patient is not readily available in a practical medical protocol. In the proposed an optimization algorithm searches for the values of the sought patient-specific parameters. The optimization algorithm is driven by the error minimization between the obtained bone architecture after one remodelling cycle and a reference one, the CT scan image of the patient, assuming an homeostasis condition in the medical image. The bone remodelling algorithm used was proposed by Doblaré and García [1], while the tissue mechanical stimulus is computed using a immersed boundary methodology, the Cartesian grid Finite Element Method, since it is well suited for the generation of FE models directly from medical images [2].

A case study involving a pre-implantation human mandible CT scan image, suggests that the procedure is able to efficiently generate simulation conditions which are closer to those physiological observed in the medical image.

Enrichment of Finite cells for Image-based analysis of Materials with complex Microstructures

Mahan Gorji* **and Alexander Düster**

Hamburg University of Technology, Am Schwarzenberg-Campus 4 (C), 21073, Hamburg, Germany,
mahan.gorji@tuhh.de

Key Words: Heterogeneous materials, computer tomography, least-squares fit, local enrichment, finite cell method

Numerical methods are widely used for solving engineering problems. For complex geometries, the finite cell method (FCM) - a combination of high-order finite elements with fictitious domain methods - is a promising approach [1]. Due to it's simple Cartesian grid, it is very efficient for modeling complex geometries. For smooth problems, the convergence rate is even exponential and therefore, the FCM performs very well. However, when dealing with heterogeneous microstructures coming from computer tomography (CT) scanner, such as, for example, hybrid metal foams or cemented sand, we face two challenges.

The first challenge is the non-smooth (staircase) geometry description given by the CT-scans. To increase the accuracy of the FCM, the geometry of the problem has to be smoothed. Here, a smooth geometry reconstruction based on a (cell-wise) least-squares fit is employed, which will be directly applied on the grayscale values of the voxel models, obtained from the CT-scans. This leads to a smooth levelset function, which then describes the geometry. This procedure has also the advantage, that it is directly applied on the raw data of the CT-scans, i.e. a time-consuming segmentation process will be avoided.

The second challenge is related to the heterogeneous materials, where the problem is not smooth anymore and thus, solving it becomes more challenging. Because of the different materials, weak discontinuities will occur at the material interfaces. These discontinuities are kinks in the solution, i.e. displacements, and jumps in the derivatives, i.e. stresses and strains. Since the FCM uses only smooth polynomials, it is not possible to capture the discontinuous part of the solution accurately and therefore, the convergence rate deteriorates. To overcome this issue, the FCM is extended by the local enrichment, which is based on the hp-d method combined with a high-order partition of unity (PUM) approach [2]. With this approach, the discontinuities in the heterogeneous materials can be captured very precisely.

In this contribution, the proposed approaches are explained and then, numerical examples are presented.

Key Words: Spectral Cell Method, Enrichment, Mass Lumping, Explicit Dynamics, Guided Wave based Condition Assessment

In recent years, Guided-Waves (GW) based assessment has evolved into a potent field of Structural Health Monitoring (SHM). In this context, data driven methods are often found lacking. To boost performance, model-based evaluations can be used; these rely on transient analysis of simulations of the structure, where damage is detected by incrementally updating a numerical model as to match the recorded signal. In this task, the main challenge lies in providing an adequate Ansatz space for the simulation of high frequency modes, whilst automatically discretizing potentially complex structures and damage configurations. With the spectral cell method, voids in the domain can be represented independently from the mesh, while the Gauss-Lobatto-Legendre nodal configuration delivers high order shape functions, and enables the direct application of explicit solvers by virtue of the nodal quadrature method. This last advantage, however, is contingent on the use of mass lumping procedures over intersected elements, due to the customized quadrature rules used to resolve discontinuous integrands. For this, HRZ lumping can be applied as in Ref. [1], while an alternative based on moment fitting was recently suggested by the authors [2].

In this contribution, we aim at representing a more generalized set of features, such as cracks or inclusions. This is achieved via partition of unity enrichment functions, and a new moment fitting approach to lump the mass of enriched elements, resulting in a block-diagonal mass matrix. To render the mass matrix fully diagonal, eigenvalue decomposition of the system of equations can then be performed. We assess the stability of the method by considering a unit-size enriched element. Finally, its capabilities are demonstrated on the illustrative 3D modeling example of a cracked plate.

Finite Cell Method using Boolean Operations for Multi-Material Problems

Márton Petö[1]*, Fabian Duvigneau[1], Sascha Eisenträger[2] and Daniel Juhre[1]

[1] Otto von Guericke University Magdeburg, Germany, marton.petoe@ovgu.de
[2] University of New South Wales, Sydney, Australia, s.eisentraeger@unsw.edu.au

Key Words: Finite Cell Method, Multi-Material Problems, Local Enrichment, Boolean Operations, Octree-Decomposition, Discontinuous Integrands

The Finite Cell Method (FCM), combining an unfitted discretization via Cartesian meshes and higher order shape functions, is an accurate and efficient tool, especially when it comes to the simulation of highly complex geometries [1]. The discontinuous integrals over cut elements are often computed using an adaptive integration scheme based on an Octree-Decomposition (OTD), resulting in a set of disjoint sub-cells over which the integral is computed individually. While the popularity of this approach is justified due to its robustness and easy implementation, high accuracy requirements often lead to a serious computational overhead due to the large number of generated integration points.

In our contribution, the Boolean FCM (B-FCM) approach proposed by Abedian and Düster [2] for porous media is further extended. Thus, the aim of this contribution is twofold: (i) application of the B-FCM to multi-material problems and (ii) combination with the local enrichment technique to accurately capture the weak discontinuities in the displacement field over cut cells in elastic problems [3]. The proposed B-FCM approach is based on the standard space-partitioning via OTD for integration purposes, however, it relies on Boolean operations. These are realized by introducing unique *Boolean labels* for each sub-cell. This serves two goals: (i) steering the OTD, such that a set of overlapping sub-cells is obtained in which the integration points can be distributed much more efficiently and (ii) modifying the integrand by Boolean operations over the individual sub-cells, such that the overlapping nature of the sub-cells is taken into account. Thus, the integral value over the entire cut cell is not changed. Using the proposed B-FCM approach, a significant reduction in the number of integration points by 70-80% can be obtained, which leads to major time savings when dealing with multi-material problems both in 2D and 3D applications. Furthermore, it should be noted that despite the impressive decrease of the number of integration points, the accuracy of the numerical integration is not affected.

Improving the Robustness of the Finite Cell Method for Finite Strain problems

Wadhah Garhuom* **and Alexander Düster**

Hamburg University of Technology, Am Schwarzenberg-Campus 4 (C), 21073, Hamburg, Germany,
wadhah.garhuom@tuhh.de

Key Words: Large deformations, remeshing, condition number, eigenvalues, finite cell method

The finite cell method (FCM) is a combination of an immersed boundary method and high-order shape functions [1]. Since the geometry of the underlying problem is embedded into a simpler domain, it can be discretized using a Cartesian grid. This makes it suitable for modeling complex geometries such as structures generated from additive manufacturing or metal foam-like structures.

The Simulation of structures, including large deformations and finite strains, poses multiple challenges. The severe distortion of the mesh may significantly affect the accuracy and robustness of the numerical method and restrict it to smaller deformations than required. This problem is particularly present in the FCM, where complex geometries are discretized with a non-conforming Cartesian grid introducing a fictitious material with very low stiffness. In order to improve the FCM's robustness, we propose a global remeshing strategy to allow the nonlinear computation to proceed even for very large deformations where the distortion of the cells becomes significant [2]. The main idea is to perform a computation up to a specific deformation state where the distortion of the cells becomes critical. Afterwards, a new mesh is introduced to be able to continue the analysis.

Also, fictitious domain methods such as the FCM suffer from ill-conditioning especially when broken cells possess a very small volume fraction of the physical domain. One way to improve the conditioning is to introduce a very soft material in the fictitious domain. However, this method can modify the solution significantly because of the large stiffness added to the system. To this end, we apply and adapt a more efficient stabilization technique proposed by Loehnert [3] to improve the condition number of the FCM without affecting the solution significantly. In this approach, only the modes causing high condition numbers are stabilized for each broken cell, based on the eigenvalues of the cell stiffness matrix. The performance of the proposed methods will be illustrated using different numerical examples.

Key Words: Isogeometric Analysis, Immersed Methods, Numerical Integration

We present an efficient and robust integration method to deal with volume representations (Vreps) in isogeometric analysis. In contrast to boundary representations (B-reps), the building blocks of V-reps are B-spline or NURBS (Non-Uniform Rational B-Spline) trivariates that generally involve trimming. While the related theories have been established in our precedent works [1, 2], here we focus on the corresponding algorithms to generate quadrature meshes for trimmed trivariates, including: (1) decomposition of a trimmed element into a collection of cells where the standard Gauss quadrature rule can be applied, and (2) reparameterization of the involved trimming surface in each cell as a Bezier surface. In particular, we adopt the marching-cubes cases [3] as the base cases and develop a corresponding decomposition for each of them to minimize the number of the resulting cells. Such a cell can be a hexahedron, wedge, pyramid, or a tetrahedron. On the other hand, trimmed elements that do not fit into one of the base cases are reparameterized using a novel strategy based on the use of folded decompositions [4]. In the end, we present several 3D examples to show the robustness of the proposed method.

Key Words: *Unfitted, embedded, immersed, finite elements*

In this work, we analyse the links between ghost penalty stabilisation [1] and aggregation-based discrete extension operators [2] for the numerical approximation of elliptic partial differential equations on unfitted meshes. We explore the behavior of ghost penalty methods in the limit as the penalty parameter goes to infinity, which returns a strong version of these methods [3]. We observe that these methods suffer locking in that limit. On the contrary, aggregated finite element spaces are locking-free because they can be expressed as an extension operator from well-posed to ill-posed degrees of freedom. Next, we propose novel ghost penalty methods that penalise the distance between the solution and its aggregation-based discrete extension. These methods are locking-free and converge to aggregated finite element methods in the infinite penalty parameter limit. We include an exhaustive set of numerical experiments in which we compare weak (ghost penalty) and strong (aggregated finite elements) schemes in terms of error quantities, condition numbers and sensitivity with respect to penalty coefficients on different geometries, intersection locations and mesh topologies. We will also discuss novel discrete extension operators that are well-posed for high order methods. Instead of considering extrapolations of the interior basis, we propose modified modal bases that do not involve high order extrapolation.

Key Words: Unfitted finite element methods; embedded methods; weak boundary conditions; Taylor expansions; high-order methods; shifted boundary method; consistency and convergence analysis.

The Shifted Boundary Method (SBM), introduced in [1], is an approximate domain method, falling in the broader class of un unfitted/embedded/immersed methods. In the SBM, the location where boundary conditions are applied is *shifted* from the true boundary to an approximate (surrogate) boundary, and, at the same time, modified (*shifted*) boundary conditions are applied. Since its appearance, the method has proven to be both flexible and robust in a variety of different applications, ranging from fluid-dynamics to solid mechanics, from heat transfer to electrostatics (see, e.g., the references in [2, 3, 4]).

The comprehension of the mathematical foundations of the method has accompanied its practical application in real-life situations. The analysis of the mathematical properties of the SBM highlights – in particular – sufficient conditions on the geometry, the unfitted mesh and the shifted boundary operator that guarantee the well-posedness of the SBM discrete variational formulation. This is accomplished through the fulfillment of suitable *coercivity* or *inf-sup conditions*, which can be checked in practice as they depend in an explicit way upon known quantities.

We will report our results in two different – somehow opposite – situations, namely the case of domains with corners [2] in which the physical solution is expected to exhibit singularities, and the case of domains with very smooth boundary, where the expected smoothness of the solution naturally suggests the use of a high-order approximation of the boundary operator [4]. We will also discuss the treatment of non-Dirichlet boundary conditions [3], as well as some open problems remaining in the analysis.

Numerical Characterization and Evaluation of Additive Manufactured Parts in Geometrical Multiscale Computational Models

Oguz Oztoprak[1*], David Briels[1], Felicitas Leithner[1], Carla Matthäus[1], Ahmad Saleem Nouman[1], Stefan Kollmannsberger[1] and Ernst Rank[1]

[1] Technical University of Munich, Arcisstr. 21, 80333, Munich, Germany

Key Words: Finite Cell Method, Additive Manufacturing, Numerical Homogenization

Additive manufacturing (AM) in construction is a rapidly growing research field due to the increased geometric freedom, process automation and design optimization that it offers. The individualized part design promotes the construction of structural elements with exceptional physical properties. However, the realization of such elements highly depends on understanding the geometrical multiscale nature of the structures. As resolving the locally varying properties of AM components in a construction scale analysis is impractical, conventional structural analysis tools are not readily equipped to handle AM parts. A proper dimensional reduction process that can effectively deal with the geometric complexities of AM components is needed to represent the parts on the construction scale analysis.

In this contribution we propose such dimensional reduction process and illustrate its effectiveness in combination with a construction scale structural analysis. The dimensional reduction process can be realized by the homogenization of thermal and mechanical properties of the parts. By virtue of being a fictitious domain method with high-order finite elements, the Finite Cell Method (FCM) [1] is well-equipped to handle the individualized part geometries. Two cases with practical relevance are considered: a concrete wall element with internal cellular structures and a space frame with individualized 3D printed node topologies. In the case of the wall element, the thermal transmittance is chosen to represent the homogenized thermal behavior. The numerical results are validated by physical experiments. The bending and axial stiffness are used to characterize the homogenized mechanical behavior of the nodes. The numerical studies utilize massively parallel machines to solve large equation systems with many millions of unknowns [2], demonstrating the scalability of the approach to handle larger parts and complex constructions.

On numerical integration of cut finite elements and cells

Alexander Düster* **and Wadhah Garhuom**

Hamburg University of Technology, Am Schwarzenberg-Campus 4 C, 21073 Hamburg, Germany,
alexander.duester@tuhh.de, https://www.tuhh.de/skf

Key Words: Fictitious domain methods, cut cells, numerical integration, quadrature, adaptive integration, octree, moment fitting, nonlinear problems, finite strains

Fictitious domain methods are of increasing interest since they do not require the generation of body-conforming finite element meshes. Therefore, fictitious domain methods are suited for problems with complex geometries. The finite cell method (FCM) is a combination of the fictitious domain approach with high-order finite elements. Thanks to the use of Cartesian meshes, the pre-processing, i.e. mesh generation is significantly simplified. Due to the fact that the applied meshes do not conform to the geometry of the problem, special care has to be taken with respect to the numerical integration of the weak form, the local refinement of the approximation as well as the treatment of boundary conditions.

The presentation will focus on the numerical integration of cut finite elements and cells arising in fictitious domain methods. First, a short overview of existing quadrature schemes will be given. Then, the moment fitting approach will be discussed in more detail. We will present some recent advances related to the moment fitting increasing its efficiency and robustness with respect to the computation of nonlinear problems. Emphasis will be placed on the question of how non-negative weights influence the robustness of the finite cell method. The investigations to be presented will range from the integration of polynomials and arbitrary functions to the solution of problems of solid mechanics applying the finite cell method. To this end, we will consider linear elastostatic problems as well as nonlinear solid mechanics problems including hyperelasticity and elastoplasticity at finite strains.

Key Words: *NURBS, Open-source, cgFEM*

The most common CAD software in engineering use Non-Uniform Rational B-Splines (NURBS) to define the geometry of the models. This form of representation has important advantages from a design point of view, but it is a major obstacle for most CAE software. Only the most advanced finite element codes such as NEFEM or IGA preserve the NURBS representation of the geometries, while most commercial codes use approximate models.

Within the research line of the Cartesian grid Finite Element Method (cgFEM), we are interested in the numerical resolution of wave propagation problems. This type of simulation requires a faithful representation of the domain since small variations in the geometric model can lead to completely different solutions. The definition of geometry has consequences at many different stages of the analysis process (mesh-geometry intersection, operator evaluation, boundary condition imposition...) and it is necessary to have a wide range of tools for handling geometric issues. Although geometric modelling using NURBS is standard, to the author's knowledge, there is no library that offers all the necessary functionalities for analysis purposes.

In this work, we present the NURBSLAB toolbox. This MATLAB library contains all the functions we have developed for handling NURBS in the cgFEM context, and it is available to the scientific community under GNU license. We evidence the enhanced functionalities of our implementation in comparison with other available alternatives. We also show its application within the cgFEM framework and the use of some special features to improve the robustness of the analysis process.

Penalized Direct-Forcing method and power-law-based wall model for Immersed-Boundary numerical simulations of obstacles in turbulent flow

Idris Hamadache[1]*, Michel Belliard[1] and Pierre Sagaut[2]

[1] French Alternative Energies and Atomic Energy Commission (CEA), DES, IRESNE, F-13118 Saint-Paul-Lez-Durance, France, - idris.hamadache@cea.fr and michel.belliard@cea.fr

[2] Aix-Marseille University, CNRS, Centrale Marseille, M2P2, Marseille, France - pierre.sagaut@univ-amu.fr

Key Words: Immersed Boundary Method, Penalized Direct Forcing, Explicit power-law wall model

This work is in the context of the safety-system development for the new generations of nuclear power plants. We wish to model the turbulent flow inside an industrial passive-safety device, the in-vessel flow limiter, based on the fluidic-diode principle [1]. Our goal is to design and optimize its shape. This shape optimization would need a lot of computations, each one with a specific mesh relative to the evaluated shape, followed by a statistical treatment.

In order to avoid the time consuming phase of re-meshing, we use the Fictitious Domain approach. Using an in-house industrial software, we face the constraint to not being able to modify the physical-problem governing equations in the code. Taking into account this fact, we choose the Penalized Direct Forcing method, a merge of the Penalty and Direct-Forcing (DF) methods [2]. It consists in a penalized forcing term, written in a DF formulation, added to the governing equations for taking into account the immersed boundaries.

Considering industrial turbulent-flow problems computed by RANS approach and not-resolved boundary layers, we need an appropriate immersed wall treatment. An immersed power-law-based wall model is chosen because its ability to model the velocity profile inside the whole boundary layer [3]. This is important due to the non-uniform distribution of the forced-node distances to the immersed wall. Moreover, this wall model has the advantage to be explicit and to not rely on an iterative procedure for the friction velocity determination. Therefore, coming from our previous directional linear interpolation technique [2], we have implemented the power law approach into our PDF method.

Using a Finite-Element version of our PDF method, we validate this approach on analytical-test cases and present our results concerning the in-vessel flow limiter industrial-test case.

Key Words: Fictitious domain, levelset, optimal accuracy

Geometrically unfitted methods, i.e. the numerical methods using the computational meshes that do not fit the boundary of the domain, and/or the internal interfaces, have been widely used in the computational mechanics for decades. Their classical variants (Immersed Boundary or Fictitious Domain methods) are easy to implement but can suffer from poor accuracy. More recent approaches, like XFEM and CutFEM enjoy the optimal accuracy at the price of a considerable sophistication wrt the implementation: they introduce the integrals on the actual boundary and on the parts of the mesh cells cut by the boundary (the cut cells) so that a non trivial numerical integration is required.

In this talk, we present an alternative unfitted method – ϕ-FEM, first introduced in [1, 2], then extended to less academic problems in [3]. As in CutFEM/XFEM, we suppose that Ω is embedded into a simple background mesh and we introduce the active computational mesh $\mathcal{T}_h$, getting rid of the cells lying entirely outside the physical domain. The general procedure is as follows: we extend the governing equations from Ω to Ω_h (the domain of $\mathcal{T}_h$) and write down a formal variational formulation on Ω_h without taking into account the boundary conditions on $\partial\Omega$; we then impose the boundary conditions on $\partial\Omega$ using an appropriate ansatz or additional variables, explicitly involving the level set ϕ which provides the link to the actual boundary; finally, we add an appropriate stabilization to guarantee coerciveness/stability on the discrete level. This approach allows us to achieve the *optimal accuracy* using the usual FE spaces and the usual numerical integration: all the integrals in ϕ-FEM can be computed by standard quadrature rules on entire mesh cells and on *entire facets*. FE of *any order* can be straightforwardly used. The geometry is naturally taken into account with the needed optimal accuracy: it suffices to approximate the levelset by piecewise polynomials of sufficiently high degree.

Key Words: Subsurface Flow, Phreatic Surface, Numerical Simulation, Level-Set Method, Finite-Volume Discretization, Ghost-Fluid Method

Numerical simulation of the density-driven flow in partially saturated aquifers is a challenging field of great practical importance. Robustness of the numerical methods should allow computations on domains whose geometry and hydrogeological structure approximate real-world geological formations (cf. e.g. [1]). The mobile liquid phase (solution of salt in water with variable concentration) saturates only a part of the domain. The flow of this phase is essentially influenced by dynamics of the interface between the saturated and unsaturated subdomains (the s.c. phreatic surface), as well as by gradient of the density.

In our talk, we consider two approaches for modeling this setting: The Richards-like model imposes a uniform system of PDEs in the whole domain [2]. In contrast to it, the phreatic surface can be considered as a moving boundary of the saturated subdomain and represented by the level-set approach. On this interface, the boundary conditions for the flow model are treated by the ghost-fluid method [3]. We compare these the approaches to investigate their limitations and computational aspects.

In our implementation, the systems of the PDEs are discretized by a vertex-centered finite-volume scheme. For the solution of the discretized systems linearized in the Newton's method, we apply the geometric multigrid method with ILU smoothing. The solvers is parallelized. We present results of the numerical experiments.

Key Words: *Condition number, Ghost penalty, Immersed boundary method, Nitsche's method, Poroelasticity, Unfitted finite element method*

The complex geometries of practical problems bring about a great challenge to the preprocessing of the standard finite element method (FEM), wherein the mesh conforms to the physical domain. An unfitted FEM with the physical domain embedded in a relatively simple mesh is a promising substitute for the fitted FEM for such cases. However, the use of the unfitted FEM for poroelasticity problems with continuous interpolation is seldom reported. Hence, in this paper, we propose a symmetric weak formulation based on the modification of Nitsche's method for fully coupled two-field poroelasticity. Furthermore, three stabilization terms based on the ghost penalty method are introduced to address the ill-conditioning caused by the extreme cut. The fluid pressure Laplacian method was employed to stabilize the pressure at the early stages in cases of small permeability and/or time step when P1P1 interpolations are employed.

The overall performance of the proposed methodology was evaluated through detailed numerical experiments. The methodology demonstrated excellent accuracy. The introduction of three ghost penalty terms enormously reduced the condition number, and the resulting condition number is at the same level as or close level to that of the fitted FEM. More importantly, they do not lead to great consistency errors, and the optimal convergence rates are preserved. Both the conditioning numbers and accuracies are approximately independent of the cut ratio. Furthermore, neither the accuracy nor the conditioning is very sensitive to the ghost penalty parameters.

Voxel-based Simulations of Ductile Crack Propagation through Metal Matrix Composite Microstructures based on Eigenerosion and Finite Cells

Dennis Wingender[1*] **and Daniel Balzani**[1]

[1] Ruhr University Bochum, Institute for Computational Engineering, 44801 Bochum, Germany,
{dennis.wingender,daniel.balzani}@rub.de

Key Words: Ductile fracture, Finite strains, Eigenerosion, Finite Cell Method, Metal Matrix Composites

In many engineering processes, e.g., mechanized tunneling, the efficiency of drilling processes strongly depends on the wear of the tools applied on the machine. In case of tunnel boring machines, cutting disks as well as chisels are used as mining tools, which consist of a metallic body armored by metal matrix layers. Those underlie the wear mechanisms abrasion and surface spalling. The latter is governed by subcritical crack propagation on the microscale under cyclic loads. Hence, the microstructure morphology and the material properties of the constituents strongly influence the resistance against crack propagation and thus against surface spalling.
In this contribution, a framework for the simulation of ductile crack propagation through metal matrix composite microstructures is presented. Therein, the eigenerosion approach as presented in [1] and its implementation for small strains in [2] are extended to an algorithmic scheme for finite strains and ductile fracture. For the ductile constituents, the finite strain J_2-plasticity formulation in [3] is applied. In order to efficiently simulate microstructures based on voxel data, an algorithm combining the extended Eigenerosion approach with the Finite Cell Method as introduced in [4]. As major part thereof, the mesh is refined adaptively at the crack tip by transforming the subcells of those finite cells at least containing one eroded subcell into single finite elements. The occurring hanging nodes are managed following [5]. In our approach, a special cell arrangement is constructed which minimizes the number of cells on the one hand and on the other hand, maintains a suitable aspect ratio of the cells' edge lengths. This aspect ratio may be irrelevant just for the integration in the subcells, but as soon as the subcells are transformed to separate elements at the crack tips the regularity of the elements becomes important. By evaluating results of simulations at the microscale, is it is shown that failure of the material can be investigated based on the proposed numerical scheme.

A droplet-phase approach to solve thin-film flows

Anand Bharadwaj S[1], Pratik Suchde[2] and Joerg Kuhnert[3]

[1] Fraunhofer ITWM, Kaiserslautern, anand.bharadwaj@itwm.fraunhofer.de
[2] University of Luxembourg, Luxembourg, pratik.suchde@itwm.fraunhofer.de
[3] Fraunhofer ITWM, Kaiserslautern, joerg.kuhnert@itwm.fraunhofer.de

Keywords: *Droplet-phase, Thin-film flows, SPH, DEM, 2D Manifolds*

Thin-film flows, observed in varied applications, are commonly seen in automobiles moving through rain. The prediction of the behaviour of such films is an important aspect that needs consideration during the design of vehicles with regard to their effect on exterior sensors, changes in aerodynamic behaviour, seepage of water into parts of the vehicle, etc. The droplet-phase model is a novel method that models the development and evolution of thin-films in the form of droplets. It consists of moving droplets on a 2-D manifold and allows the use of computational resources more efficiently in comparison to fully 3-D Navier-Stokes solvers to capture the same behaviour[1]. In the droplet-phase approach, the 2-D manifold contains droplets. The film height at a given location, is a function of the location of droplets in its neighbourhood. The momentum equation takes into consideration various forces that act on the droplet (hydrostatic pressure, viscous forces, etc.), and solves for the velocity of the droplets. The derivatives are estimated using weighting kernels and their derivatives, as in SPH. The advection of droplets at the solved velocity results in the evolution of the height function. In this approach, therefore, the evolution of the height function is captured through the movement of droplets that are treated as discrete particles, as in DEM, although the approach considered in the present work does not feature a contact model for droplet collisions. This facilitates the use of this approach for both DEM simulations such as droplets in free-flight as well as for thin-film flows. In this work, comparisons of the droplet-phase approach with shallow-water models are made for both 1-D and 2-D test cases. The results show the reliability of the method and highlight the potential of this method to solve problems with thin-films.

Key Words: *meshfree methods, HOTM, thermomechanical coupling, additive manufacturing*

Powder-based Additive Manufacturing (AM) technologies, such as Powder Bed Fusion (PBF) and Directed Energy Deposition (DED) technologies, enable high degrees of design freedom for optimal functional features and customized products at reasonable costs. One of the leading research efforts in AM technology focuses on the rigorous product quality control by reducing the material defects in the microstructure and enhancing the reliability and robustness of the manufacturing processes. An attractive method for addressing this challenge is numerical modelling and predictive simulations [1-3]. We present a Lagrangian meshfree simulation scheme for AM technologies of metals at the powder scale based on the Hot Optimal Transportation Meshfree (HOTM) method [4]. In the simulations, metallic powder particles are modelled explicitly as deformable bodies according to their size and shape distributions measured in experiments. The strongly coupled thermomechanical response of the material is simulated by a thermo-viscoplasticity model. The conservation of linear momentum and energy equations are solved simultaneously to predict the deformation, temperature and phase evolution of the particles. The computational framework is capable of predicting the granularity and fine-scale physics in the problem, such as powder particle thermodynamics, material phase evolution and fluid-structure interactions, which primarily affect the mechanical behaviour and heat transfer in the aggregation of discrete particles [5]. Furthermore, high-fidelity predictions of the defect formation in the microstructure of 3D printed metallic parts, including voids, micro-cracks, unmelted/partially melted second phase inclusions, can be achieved. The proposed approach is validated in the applications of Laser PBF-AM process and DED technologies of metals.

A novel implicit material point method for ductile fractures

Emmanouil Kakouris[1*] **and Savvas P. Triantafyllou**[2]

[1] Roughan and O' Donovan, Dublin, Ireland, e-mail: manolis_kakou@hotmail.com

Key Words: MPM, phase field, ductile fracture

Predictive modelling of ductile fracture is of extreme interest to the engineering community as it pertains to various applications, e.g., fracture propagation in metal alloys. Cracks propagating in solids are governed by complex phenomena such as crack initiation, multiple crack branching, or crack arrest. Mesh distortion errors that are inevitable in large displacement FEA hinder the fidelity of such simulations where the deformability of mesh affects the resulting contact forces and corresponding failure surfaces.

Material point methods have been shown to provide high fidelity solutions for domains undergoing large displacements and/or large strains [1]. Rather than relying on the notion of a deforming mesh, material point methods introduce a particle based approximation for the deformable body that move within a non-deforming mesh. This introduces a considerable advantage as opposed to purely particle based methods as the continuum approximation is preserved thus releasing the requirement for high particle densities.

To this point, material point implementations for brittle fracture have proven efficient in tackling quasi-static crack propagation in terms of computational simplicity and robustness. The Phase Field Material Point Method (PF-MPM) has been successfully introduced [2] for quasi-static brittle fracture problems. In this, the phase field is resolved at material points and mapped onto grid nodes where the phase field governing equations are solved.

In this work, the PF-MPM is originally extended to account for fractures propagating in ductile materials. A NURBS based background grid is deployed to treat cell-crossing errors. Driven by the developments in [3] the basis is properly extended at the boundaries to provide stable fracture patterns. The merits of the proposed scheme are investigated through a set of benchmark cases.

Discrete Element Simulation of Compaction and Sintering of Ceramic Powders

Gilmar Nogueira[1*], Christophe Martin[1]

[1] Univ. Grenoble Alpes, CNRS, Grenoble INP, SIMaP, Grenoble F-38000, France.

E-mail: gilmar.nogueira-junior@grenoble-inp.fr

Key Words: *Powder Compaction, Sintering, Ceramic, Discrete Element Method*

The Finite Element Method (FEM) is an established method for the simulation of powder metallurgy processes on a large scale. However, it cannot explicitly consider the particulate nature and the composite aspect of powders. An alternative simulation method is the Discrete Element Method (DEM) which considers each particle and its interactions with its neighbors. For large-scale problems, these are challenging simulations due to the high computational cost associated with representing a very large number of particles.

In the present work, we present a DEM model that can simulate two important stages of the powder metallurgy process: compaction and sintering. We use the in-house developed code dp3D [1] dedicated to materials science. Spherical discrete elements in the code model porous agglomerates which indent each other during compaction and sintering.

In the compaction process, uniaxial die compaction, using an upper and lower punch, has been implemented on a cylindrical geometry. The process kinematics are decomposed into a compression stage, unloading, and ejection of the pellet. Interactions between the particles and the die are considered elastoplastic, by implementing and adapting a large-density model [2]. A qualitative approach is followed in the sintering process, using the Bouvard Pan model [3, 4].

The results are in good agreement with experimental data and FEM simulations, regarding stress-strain curve, density gradient, elastic spring-back, and final geometry. The simulations show that the friction coefficient is the primary factor to induce a density gradient in the pellet. The pellet is more porous in its center when compared to the regions close to the punches. This density gradient induces a non-homogeneous sintering, which results in a final geometry that is no longer cylindrical. This so-called diabolo effect in the sintered pellet was previously simulated by FEM, but to the author's best knowledge, it is the first time that it has been reproduced by DEM.

Force method conception using transfer matrix to apply to multiphase flow by one-by-one corresponding Particle-Cartesian cell (*P*/*CC*) model

Junya Imamura[1*]

[1] 31-9-803, Honcho, Wako-shi, Saitama, 351-0114 JAPAN, jimamura@ra2.so-net.ne.jp

Key Words: *Force method to continuum mechanics, Transfer matrix method, Multiphase flow, Cauchy-Riemann equations, Conjugate variables, One-by-one corresponding Particle-Cartesian cell model, Locking-free finite element method*

The objective of this study is to develop a force method for application in the multiphase flow by the one-by-one corresponding Particle-Cartesian cell model, which is previously proposed in [1].
Displacements and forces continue at the surfaces between phases, whereas strains discontinue. Meanwhile, the proposed force method is applicable for continuum mechanics and differs from the conventional method for the framework, and it is referred to as Continua-work in this study. In this study, two types of schemes are presented: the first is as follows, and second is built using the so-called separation parameter method.

The state vector: {displacement, stresses}: $\{\boldsymbol{U},\nabla\boldsymbol{F}\}$ continues and the strains represented by $\{\nabla\boldsymbol{U}\}$ discontinue in general to satisfy the week solution of the virtual work according to the FEM conception. One of the proposed force methods uses incomplete three-fold third-order element, consisting of parameter vector: $\{\boldsymbol{U},\nabla\boldsymbol{F}\}_k$ on the vertex node k. Therefore, the element function is represented by parameter vector: $\{\boldsymbol{U},\nabla\boldsymbol{F},\nabla\nabla\boldsymbol{F},\cdots\}_0$ on the local origin. The strains are represented by $\{\nabla\boldsymbol{F}/\nu\}$ of the transfer matrix, where ν is kinetic viscosity.

The transfer matrix, also known as the reduction matrix, can represent state vector $\{\boldsymbol{U},\nabla\boldsymbol{F}\}_b$ on b by state vector $\{\boldsymbol{U},\nabla\boldsymbol{F}\}_a$ on a, even though a rigid member (rigidity $G = \infty$) is included. This is because the forces are transferred, and they continue at the boundary. In beam theory, it exists as a strong solution; however, for continua, it exists only week solutions.

The simultaneous equation is constructed by the virtual work principle. Cauchy-Riemann equations defined in two dimensions must be satisfied as necessary conditions for a robust scheme because the strain and stress represented by $\{\nabla\boldsymbol{U},\nabla\boldsymbol{F}\}$ have four components (freedom). In the same way in three dimensions, as constraint conditions, so-called conjugate variables concept has been proposed.

Accordingly, the equilibrium equation represented by $\{\boldsymbol{U}\}_k$ and $\{\nabla\boldsymbol{F}\}_k$ for multiphase flow represented with different ν has been obtained. In addition, another scheme is explained in the full paper.

Modeling of Solid Phase Processing of Aluminum Alloys using Smoothed Particle Hydrodynamics and Physics-Based Constitutive Material Model

Ayoub Soulami*, Lei Li, Glenn Grant

ayoub.soulami@pnnl.gov

Pacific Northwest National Laboratory. Richland, WA. 99352. USA

Abstract

Solid Phase Processing (SPP) is a high-strain process applied to materials during fabrication to produce high-performance alloys, semi-finished products, and engineered assemblies without the requirement to melt the constitutive materials. This emerging manufacturing platform delivers extraordinary performance in metal alloys, relative to identical materials produced by conventional manufacturing routes. Friction Stir Welding/Processing (FSW/FSP), Friction Stir Extrusion (FSE), and Shear Assisted Processing and Extrusion (ShAPE) are some of the advanced manufacturing techniques part of the SPP family. Simulation of such processes remains an ongoing challenge in computational mechanics and computational material science. There are difficulties associated not only with the formulation of physics-based models to accurately predict material behavior at the solid-state, but also with the computational methods required to treat extremely large material deformation. A physics-based material model accounting for the attributes from lower length-scale, such as grain size, dislocation density, dynamic recrystallization and recovery, to the bulk thermomechanical material behavior with varying strain rate and temperature history will be presented. This model was incorporated into a continuum-scale smoothed particle hydrodynamics (SPH) model to simulate FSP, FSE, and ShAPE tube extrusion of aluminum alloys. Due to its inherent meshfree and Lagrangian feature, SPH model is well-suited to modeling processes with severe deformation. Numerical results are validated with the experimental data, demonstrating a promising structure-properties linkage achieved by the model. The proposed physics based SPH model leads to an improved prediction and better understanding of the microstructural evolution and thermomechanical behavior of the material across SPP processes, enabling an accelerated and cost-effective development effort.

Modelling of forming processes using the Particle Finite Element Method (PFEM).

Key Words: *Forming processes, thermo-mechanical problems, Particle methods, PFEM*

In this work we present the latest advances in the Particles Finite Element Method (PFEM) for the numerical modeling of forming processes. In the recent past, very good results of the method have been shown in the simulation of 3D cutting problems. The method has very good capabilities for treating large deformations in massive volumetric parts. Now the method is applied and extended to other forming operations: forging, blanking, minting, machining, etc., for metals and other materials.

One of the important aspects of these manufacturing techniques is the interaction with the molds and dies. Deformable contact interactions are needed to obtain a close correspondence between numerical and experimental results. The characterization of the thermomechanical interaction with the coatings of the tool plays an important role. Advances have been made in meshing techniques for treating three-dimensional parts and for the modeling deformable contact.

The characterization of friction and wear of the forming tools can be modeled considering also the lubrication on the surfaces. The purpose is to obtain the characteristics of the final shape of the workpiece, the areas that experience large plastic deformations and the residual stresses that remain in the processed material. This information is very valuable for the optimal design of the manufacturing operation.

To show the virtues of the method, several examples of forming operations are presented. The capabilities of the method are discussed, as well as the accuracy of the solutions.

Multiscale, multiphysics modeling of wave propagation in anisotropic saturated porous media

Weijian Liang[1] and Jidong Zhao[1*]

[1] Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, China

[*] Corresponding author: jzhao@ust.hk

Key Words: *Multiscale modelling, hydro-mechanical coupling, wave propagation, saturated soil, anisotropy*

We present an innovative multiscale, multiphysics coupling approach to solve a class of dynamic problems in saturated granular media. The approach is formulated by coupling dual-phase material point method (MPM) with the discrete element method (DEM), where the MPM is used to solve macroscopic deformation and pore pressure of saturated porous media while the DEM is attached to each material point to derive the nonlinear mechanical response of the solid matrix of porous media. Based on the Terzaghi's effective stress principle, the DEM receives deformation gradient from its attached material point to compute the effective stress quantities for the MPM and the pore fluid is considered by the continuum method MPM via the *u-v-p* formulation. A semi-implicit integration scheme is derived to circumvent the limitation on small-time steps imposed by incompressibility of interstitial fluid and the potential low permeability. The developed approach is further employed to model the wave propagation in saturated anisotropic granular sand. We demonstrate that multiscale simulation can capture a rich array of patterns of wave propagation and offer direct link and explanation of these phenomena with their underlying microstructural mechanisms.

Particle-based Numerical Analysis of Jet Flow from a Pipe

Norimasa Yamasaki[1*], and Haruka Obe[1]

[1] Nippon Steel Corp.,20-1 Shintomi, Futtsu, Chiba 293-8511 Japan,
yamasaki.x3s.norimasa@jp.nipponsteel.com

Key Words: *Particle-based Flow Analysis, Jet Flow, Boiling Heat Transfer*

Cooling processes are widely used in steel making processes. In some processes, plates are cooled using water flowed from pipes. Generally, cooling is performed in which water is dropped onto a steel plate by its own weight from a plurality of pipes.

In the cooling process, there is a heat transfer coefficient as an index showing the cooling capacity. In the case of steel making process, boiling heat transfer is dominant. The heat transfer coefficient at boiling condition can be estimated by the surface temperature of the plate, the water density, and the collision pressure.

However, a large amount of cooling water from a plurality of pipes stays on the plate as water pool. It is difficult to estimate the pressure that collides with the actual plate because it is cooled from above the water on the plate. Therefore, the collision pressure during cooling of the jet flow above the water pool was analyzed by the particle-based flow analysis, which is excellent in free surface analysis.

The accuracy of the calculation was confirmed by comparing with the experimental results. As a result, the experiment and the calculation showed that the larger the amount of water in the pipe laminar the higher the collision pressure tended to be. Flow analysis using the particle method has made it possible to estimate the heat transfer coefficient under a complex free surface where water pool and jet flow interfere.

Key Words: DEM, bi-elastic, self-propulsion, symmetry breaking, asymmetric collisions, energy harvesting

It has been a long discussion on the possibility to convert random Brownian motion to usefull work, also known as thermal energy harvesting, for over a hundred years in various gedankenexperiments [1]. The concept based on the Brownian ratchet deemed impossible [2]. Recently, an attempt to check the concept of Brownian ratchet using macroscopic granular gas was undertaken, showing principial possibility to convert random motion to usefull work [3]. Granular gas may perform work directly as Smoluchowski ratchet, and even more effieiently, if bi-sided (elastic and inelastic) vains are used. The question still remains, whether it is possible to build a microscopic system, converting thermal motion to work ? An asymmetric sawtooth potential might do that yielding directed current, if the particles are periodically heated and cooled [4]. We approach the problem of converting random motion to the directed one from the other side. Instead of making asymmetric external conditions, like a ratchet or a potential, we make particles asymmetric. If sides of a particle have a different restitution ratio, then it yields asymmetric collision dynamics, thus favouring certain post-collision direction. We show the main idea based on a simple collision model and present the results of DEM simulations of bi-elastic particles' ensemble.

SPH simulation of landslides as a multi-physics problem

Daniel S. Morikawa[1*], Asai Mitsuteru[2] and Haruki Osaki[2]

Key Words: SPH, Landslides, Multi-physics Problems, Finite strain elastoplasticity

Landslides are among the most dangerous geologic hazards there are. One example of a catastrophic event was observed in 2016, when an earthquake magnitude M7.3 triggered a series of landslide disasters in Kumamoto prefecture, Japan. Such event had serious consequences, one of the most remarkable being the collapse of a 200 m long bridge called Aso bridge. Given its large-scale nature, it is of great importance to develop numerical methods to study it. However, it is still to be seen a numerical method capable of accurately predict and evaluate the post-failure behavior of a landslide in an unified simulation. In this context, we propose a Smoothed Particle Hydrodynamics (SPH)-based multi-physics approach to simulate the complete landslide phenomena.

For the stable solid part of the landslide, we propose a total Lagrangian SPH formulation for Solid Mechanics problems [1] with finite strain elastoplastic stress update that can be easily adapted to any plastic yield criteria. Then, ruptured particles according to a simple rupture criterion such as establishing a threshold on the accumulative plastic strain are assigned to change its physical status to become a non-Newtonian fluid. The ruptured particles are considered to be the flowing part of the landslide, which we solve with a fully implicit Incompressible SPH (IISPH) method [2]. Finalizing the method, we arrange the coupling mechanism as a fluid-structure interaction problem in a similar way as [1]. In addition, we developed a solid-solid contact algorithm for SPH that include both the non-penetration condition and friction forces to enable the inclusion of debris material into the landslide flow.

Numerical tests include simple verification and validation examples such as the triaxial compression test with the modified Cam–Clay constitutive model. Finally, we show the robustness of the proposed method with a simulation of the Aso landslide taking the earthquake loading into account.

The P-DNS Method to Solve Particle-Laden Turbulent Fluid Flows

Sergio Idelsohn[1*], Juan Gimenez[2] and Eugenio Oñate[3]

[1] CIMNE/ICREA, Barcelona, Spain; sergio@cimne.upc.edu
[2] CIMEC/CONICET, Santa Fe, Argentina; jmarcelogimenez@gmail.com
[3] CIMNE/UPC, Barcelona, Spain; onate@cimne.upc.edu

Key Words: *Multiscale Solutions, Turbulent Flows, Particle-Laden Fluids, P-DNS*

Particle-laden flows refer to a kind of two-phase fluid flow in which one of the phases is continuously connected and the other phase is made up of small immiscible particles. Two-phase flow modeling has a wide variety of scientific and engineering applications: dispersion of contamination in the atmosphere, fluidization in combustion processes, deposition of aerosols in aerosol drugs, spread of virus in the air, rain formation in clouds, sand and dust storms, protoplanetary disks, volcanic eruptions, geological sedimentation processes, pharmaceutical sprays, liquid-fueled combustion and solid rocket motors, are examples of engineering processes that involve particle-laden flows among many others.

The equations governing interactions of particles with fluids in a particle-laden mixture have been known for many decades. However, their coupled dynamics often result in complex behavior such as preferential concentration and turbulence modulation. These are still ongoing topics of research. The starting point for a mathematical description of almost any type of fluid flow is the classical set of Navier–Stokes equations (N-S). To describe particle-laden flows, these equations must be modified for the effect of the particles.

Typically, the fluid is treated in a Eulerian frame, while the particles are treated in a Lagrangian way. However, problem with the Lagrangian treatment of the particles is that once the number becomes large, it may require a prohibitive amount of computational power to track a sufficiently large sample of particles required for statistical convergence. In addition, if the particles are sufficiently light, they behave essentially like a second fluid. This is the main objective of this presentation.

On the other hand, due to the interactions between turbulence structure and dispersed particles, turbulence characteristics of momentum and heat transport can be modified by the presence of particles. This last phenomenon is known as turbulence modulation and can lead to a significant increase or decrease in the parameters that regulate turbulence.

The authors presented in Ref. [1] a multi-scale method called Pseudo-Direct Numerical Simulation (P-DNS) [2] to study the phenomenon of turbulence modulation in a particle-laden flows. However, in that article, the particles in both, the fine scale and the coarse scale, were treated in a discrete way moving in a Lagrangian reference frame within the fluid. In this presentation, the same P-DNS method will be used to simulate the presence of particles as a continuum function that moves within the fluid. The result is similar to a fluid mixing problem, with the exception that now the coefficients that regulate the convection of one fluid with respect to the other, are obtained from a direct numerical simulation obtained on a finer scale solved offline. In this way, the need to represent each of the particles that move in the fluid is avoided.

Key Words: Discrete Element Method, Quasicontinuum Method, Granular Materials

The Quasicontinuum (QC) Method [1] was developed for quasi-static atomistic simulations where the arrangement of atoms is calculated to minimise the global potential energy of the system by using a reduced number of atoms. The method thereby reduces the number of degrees of freedom of the problem which in turn reduces the computational cost of the simulation. In pursuit of a QC method for granular systems, an implicit integration scheme for the Discrete Element Method (DEM) [2], based on the variational integrator approach [3] is developed [4]. This combines an integration scheme that is compatible with the variational structure of the QC method with a fully dynamical description required for granular systems.

This talk will extend our previous work by introducing the coarsening technique of the QC method to the dynamics of granular systems. In accordance with the QC method, a series of representative particles (or rep-particles) are chosen which become the degrees of freedom of the coarsened system and particle momenta, mass and forces of regular particles are mapped to rep-particles. The density of rep-particles can be low in regions where particles tend to experience little relative motion (such as the low inertial regime) and gradually increased in regions where higher deformations are expected. Rep-particles can be reallocated while the simulation runs and the gradual transition in rep-particle density avoids the need for handshake or boundary regions.

An overview of the QC method will be presented along with comparisons to classical DEM simulations. Our implementation of the QC method shows good statistical agreement with DEM simulations.

Key Words: *Topology Optimization, Cross-Flow Heat Exchanger, Isogeometric Analysis, Heat Exchange Performance, Pressure Drop, Manufacturing Constraints*

Heat exchangers (HXs) have gained increasing attention due to the intensive demand of performance improving and energy saving for various equipment and machines. As a natural application, topology optimization has been involved in the structural design of HXs aiming at improving heat exchange performance (HXP) and meanwhile controlling pressure drop (PD). In this paper, a novel multiphysics based topology optimization framework is developed to maximize the HXP between two fluids with different temperatures for 2D cross-flow HXs, and concurrently minimize the PD between the fluid inlet and outlet. In particular, an isogeometric analysis (IGA) solver is developed to solve the coupled steady-state Navier-Stokes and heat convection-diffusion equations. Non-body-fitted control mesh is adopted instead of dynamically remeshing the design domain during the evolution of the two-fluid boundary interface. The method of moving morphable voids (MMVs) is employed to represent and track boundary interface between these two different fluids. In addition, various constraints are incorporated to guarantee proper manufacturability of the optimized structures with respect to practical manufacturing process such as additive manufacturing. To implement the iterative optimization process, the method of moving asymptotes (MMA) is employed. Numerical examples show that the HXP of the optimized structure is greatly improved compared with its corresponding initial design, and the PD between the fluid inlet and outlet is minimized concurrently. Moreover, smooth boundary interface between two fluids and improved manufacturability are also obtained for the optimized structures.

Key Words: *Immersogeometric Analysis, Heart Valves, Isogeometric Analysis, Fluid-Structure Interaction, Open-Source Software, FEniCS*

Prosthetic heart valves have been simulated for nearly a decade [1,2], but all state-of-the-art research codes have remained in-house. This work outlines an open-source framework that is capable of industrial-scale, physiologically accurate heart valve simulations. This framework utilizes the open-source finite element software FEniCS [3] and its isogeometric extension, tIGAr [4]. The novel contributions to the simulation framework, building on the work of Kamensky et al. [5], include adding an arbitrary Lagrangian–Eulerian reference frame to the fluid problem, implementing the solid problem for the artery walls, and the inclusion of accurate material models for the artery walls and valve leaflets. These contributions enable prosthetic heart valve simulations that perform comparably to other cutting-edge analysis programs. Additionally, because of FEniCS's large user community, our framework is easier to learn, pre-process simulation inputs, and post-process results when compared to in-house codes.

Key Words: *Isogeometric analysis, Splines with extraordinary points, Trimmed NURBS, Crash Simulation, 3-point bending*

In order to improve CAE accuracy and reduce the manpower needed to transition from CAD to CAE, the use of isogeometric analysis (IGA) is an efficient approach for automotive applications. To make crash simulation models based on IGA, we started using the outer and inner trimming functions. For the parts of the body in white, approximately 80% of all parts were made using the outer trimming function. Outer trimming function is very effective and fast to generate IGA models. However, it was not a suitable option for very complex parts and parts having big holes like outer panel around the doors. Therefore, for the remaining approximately 20% of all parts, inner trimming function was initially adopted. By using this function, outer panel model was completed. However, this inner trimming function resulted in some issues. The presence of some small elements in the model was hard to avoid, which limited the size of the time step. In addition, time-consuming reconstruction work for CAD surfaces was needed. More importantly, border lines between NURBS surfaces were weakly C^0-continuous. Thus, once fracture occurs, the fracture tends to progress along the C^0 boundary which suggests that the fracture patterns are affected by the discretization of the geometry. To resolve these issues of trimmed NURBS, we used splines with extraordinary points to represent the outer panel [1, 2]. By using splines with extraordinary points, the model for the outer panel was made very fast, there were no small elements in the model limiting the time-step size, and the geometry was at least C^1-continuous everywhere. The axial crush, 3-point bending test, and simulations with hat section frame were performed to investigate the accuracy of splines with extraordinary points. It was found that splines with extraordinary points are more effective for obtaining results with high accuracy.

Key Words: *Crash, isogeometric analysis, CAD, Ricci flow, quadrilateral layout*

Isogeometric analysis (IGA) has attracted attention from academia and industry because of its high-fidelity results, ability to represent geometry exactly, and potential to streamline the engineering design-through-analysis process. However, one of the greatest challenges limiting the scope of IGA is the ability to rapidly convert CAD geometry into a set of splines suitable for engineering analysis—particularly for a wide set of shapes of industrial relevance.

In this presentation, we describe a new, mathematically rigorous, potentially automatable framework using Ricci flow and subsequent metric optimization [1] through which surface geometries can be rebuilt as sets of watertight, analysis-suitable, boundary-conforming semi-structured NURBS patches. Reconstruction of models using this framework leads to geometries that are immediately suitable for both isogeometric analysis and any additional design operations.

We demonstrate the utility of this method by rebuilding a trimmed CAD model of the US Army's DEVCOM Generic Hull vehicle [2] as a set of watertight splines. We also reconstruct the chassis of a 1996 Dodge Neon [3] from a finite element model as a set of analysis-suitable splines.

Finally, we perform crash analysis of the Dodge Neon vehicle using the reconstructed spline spaces. It is shown that the Bezier elements of the isogeometric splines can be much coarser than the quadrilateral and triangular elements of the original finite element model while still producing analysis results with much higher accuracy than those of the original model. (Here, accuracy is determined by comparing analysis results with those on refined finite element meshes.) Ultimately, this work both showcases a high-fidelity isogeometric model reconstruction paradigm and also affirms the merit of isogeometric analysis in automotive crash simulations.

Isogeometric shell analysis for aerospace engineering applications

Emily L. Johnson[1]*

[1] University of Notre Dame, Aerospace & Mechanical Engineering,
150 Multidisciplinary Research Building, Notre Dame, IN 46556, USA
eljohnson@nd.edu

Key Words: Isogeometric Analysis, Aerospace Engineering, Aircraft Structures, Penalty Coupling

While isogeometric shell analysis has many significant advantages in the design and simulation of complex science and engineering problems involving thin structures, several key challenges remain in establishing isogeometric analysis (IGA) as a robust and reliable industry standard for computational analysis. This work focuses on developing adaptable modeling and analysis approaches that enable the direct and effective use of IGA for aerospace engineering applications. The capabilities of these developments are demonstrated through the modeling, simulation, and analysis of aircraft structures.

For airframes that include numerous curved geometries that conform to the airfoil surfaces of the aircraft, IGA provides a suitable alternative to traditional finite element approaches because of its capabilities in modeling exact geometries. However, the complex designs of the airframe structures in an aircraft's wings, stabilizers, and fuselage require methods to connect multiple geometric components in the aircraft model. This is accomplished through a patch coupling method that applies to many different geometric configurations and problems through the use of dimensionally consistent penalty terms [1]. This coupling approach enables efficient analysis of the aircraft's internal support structures. Material modeling approaches are developed to identify different material property regions and subdivide the airframe structures for consistent analysis. In the future, the effective application of these approaches could also facilitate developing direct inputs to improve the design of various aircraft components within an analysis-driven computational design framework.

The presented simulation and modeling approaches for these aircraft applications highlight the adaptability and design power of incorporating IGA as an analysis tool in the aerospace industry. These developments support further improvements in computational analysis-driven design approaches for a variety of complex structures, including for aircraft applications, and offer an important step toward optimizing the efficiency, performance, and cost of many types of structures.

An Interpolating Particle Method for the Vlasov–Poisson equation

Paul Wilhelm[1*] **and Matthias Kirchhart**[1]

[1] Applied and Computational Mathematics, RWTH Aachen University,
Schinkelstraße 2, 52062 Aachen, Germany,
wilhelm@acom.rwth-aachen.de

Key Words: particle method, Lagrangian scheme, Vlasov–Poisson equation, reproducing kernel Hilbert spaces

The Vlasov–Poisson equation is high-dimensional and develops strong turbulences. Therefore grid-based methods rapidly become expensive and thus infeasible to use. Particle methods try to overcome these problems by avoiding a phase-space grid and instead moving weighted particles along their respective trajectories. While computationally less expensive, traditional particle methods produce noisy results with low convergence rates and therefore need high resolutions and remapping strategies.
We present a particle method which avoids this noise by interpolating the correct function values at each particle-position without resorting to a grid in phase-space. Furthermore using RKHS-theory we can show that interpolation using an appropriate kernel leads to optimal convergence rates.

Interpolating Vortex Particle Methods using Spline Wavelets

Matthias Kirchhart[1]

[1] Applied and Computational Mathematics, RWTH Aachen University
Schinkelstraße 2, 52062 Aachen, Germany.
kirchhart@acom.rwth-aachen.de

Key Words: vortex methods, particle methods, interpolation, splines, wavelets

Vortex particle methods are Lagrangian schemes for the vorticity formulation of the incompressible Navier–Stokes equations. Because they make use of stream functions and are based on the analytical solution of the advection equation, they possess many favourable properties: a complete absence of numerical visocity, exactly divergence-free velocity fields, no CFL condition, no LBB condition, and many more.

In this talk we extend our previous work [1] on splines for particle methods. This approach allowed us to perform long-term accurate, high-order simulations without remeshing and could compete with a state-of-the-art discontinuous Galerkin method. However, when flows develop steep gradients and particles begin to cluster the method becomes inefficient due to its lack of adaptivity.

We then present a novel approach that instead interprets a given particle cloud as a set of point values and constructs smooth interpolants on them. These interpolants make use of spline wavelets and are adaptive. On the one hand, the method is a natural extension of our previous approach. On the other hand, there is a close relationship with radial basis function interpolants. The resulting schemes have many beneficial properties and preliminary results are promising.

PROPERTY-PRESERVING DISCONTINUOUS GALERKIN METHODS FOR HYPERBOLIC PROBLEMS

Hennes Hajduk[1]*

[1] TU Dortmund University, Institute of Applied Mathematics (LS III) Vogelpothsweg 87, D-44227 Dortmund, Germany, hennes.hajduk@math.tu-dortmund.de

Key Words: Algebraic flux correction, discontinuous Galerkin methods, hyperbolic problems, limiters

Discontinuous Galerkin (DG) methods are among the most widely used numerical discretization techniques for solving partial differential equations. Their local conservation property, high order accuracy, and favorable scalability in parallel make these schemes attractive for many applications in computational fluid dynamics.

There are however, many shock-dominated problems, for which DG methods fail to produce approximations free of spurious oscillations, and might even crash. To overcome this shortcoming, we blend a provably property-preserving low order method with the corresponding high order DG target scheme. The proposed method extends the recently developed monolithic convex limiting procedures, designed originally for continuous finite elements [3, 4] to the DG setting. This algebraic flux limiter is primarily used to impose local (and global) bounds on numerical approximations [2] but extensions for incorporating entropy inequalities, as well as relaxation of the constraints in smooth regions are also possible.

In my talk, I will discuss the details of the approach, which include the sparsification of the low order method, stabilization of the numerical flux, as well as the design of the monolithic limiter. Sequential limiting for products of unknowns (originally proposed in [1]) and the preservation of global constraints, such as nonnegativity of pressure will also be touched upon. The performance of the method is evaluated for a variety of classical benchmarks for scalar conservation laws, as well as the systems of shallow water and Euler equations.

Recent Advances in Pressure-robust Finite Element methods

Christian Merdon[1*] **et. al.**

[1] Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, 10117 Berlin, Germany, Christian.Merdon@wias-berlin.de

Key Words: Navier–Stokes Equations, Pressure-robustness, Finite Element Methods

The talk focuses on a certain family of pressure-robust finite element methods based on the idea by Alexander Linke to modify the test functions, see e.g. [1]. Pressure-robustness is a favorable property of a numerical scheme if large irrotational forces appear in the momentum balance, e.g. through external forces, the material derivative or coupling terms. In case of incompressibility the irrotational parts of the forces should be fully balanced by the pressure. The velocity of a discrete scheme that is not pressure-robust may show large errors if this pressure is relatively complicated and there even can be observed a locking phenomenon with respect to the viscosity in the simplest incompressible Stokes setting.

The talk shortly recalls the ideas with some well-known finite elements and demonstrates in particular how the Bernardi–Raugel finite element method can be modified into a pressure-robust scheme of lowest order with the same number of degrees of freedom that heals the shortcomings mentioned above. Similar ideas can be used to design a well-balanced scheme for the compressible Navier–Stokes equations that also preserves mass and non-negativity of the density [2].

It is not straight-forward to preserve pressure-robustness (even for fully divergence-free schemes) in convection stabilization and (guaranteed) a posteriori error control. The talk also presents some latest progress on these issues that are mainly based on studying the underlying vorticity equation [3, 4].

Key Words: *SPH, Multiphase Flows, Meshless Methods, CFD*

Multiphase flows are frequently encountered fluid phenomena in a large range of cutting edge science and engineering problems, e.g. underwater explosion and cavitating flows. In terms of the numerical modeling of compressible multi-phase flows, the mesh-based methods are normally employed. Although SPH, as a meshless method, is inherently suited for the modeling of sharp interface problems, which has already been proven successful in industrial incompressible flows [1], the application in modelling strongly compressible multi-phase flows is still rare, mainly due to its inability to maintain a stable and accurate solution at the phase interface.

In this work, we present a robust and accurate SPH formulation for the numerical modeling of multi-phase flows with strong compressibility. An adaptive and extended Riemann solver is developed to handle materials with general equations of state and large density ratio. Numerical dissipation is applied adaptively considering the local smoothness of the flow field. The scale of SPH particles is evolved dynamically according to the local flow features to increase the efficiency of simulation. A second-order gradient estimator as well as the MUSCL-Hancock scheme are utilized to go beyond 1st order of accuracy. The proposed method is implemented in the code developed in [2]. Extensive numerical tests are carried out to validate the accuracy of the proposed numerical method in the end. Significant improvement is observed comparing to traditional SPH. The simulation results exhibit low dissipation while are able to maintain a smoothed pressure field in the mean time.

Key Words: *Nanodroplet, Molecular dynamics simulation, Impinge, Graphene*

The phenomenon of droplets' impinging on a solid surface is common in engineering applications. With the application of micro and nanotechnology in industrial processes, the impinging behavior of nanodroplets has aroused widespread interest. Graphene can be easily induced ripples and wrinkles in most cases due to its thermodynamic instability. In this paper, a series of wrinkled graphene models of sinusoidal morphologies are established, and molecular dynamics simulation is used to explore the dynamic process of nanodroplet impinging on the solid surface. The effects of nanodroplets with different droplet velocities, wrinkled graphene models of sinusoidal morphologies with various parameters, and different solid surface energy on the dynamic characteristics of nanodroplets are discussed and analyzed.

[1] 1Institute of Aerodynamics, Technische Universität München, 85748 Garching, Germany
Email: jingyu.wang@tum.de; steffen.schmidt@tum.de; nikolaus.adams@tum.de

Key Words: *Finite Viscoelasticity, TLSPH, Cavitation*

Collapsing gas or vapor bubbles may induce violent liquid jets that can create pores in membranes or tissue. These pores can be fundamental for transport processes of medicine or genes to target cells. Therefore, further investigation of the underlying physical mechanisms can improve the biomedical treatment of drug delivery and other medical applications.

We apply the meshless smoothed particle hydrodynamics (SPH) method to simulate cavitation and bubble collapse processes near soft tissue. Using the total Lagrangian SPH (TLSPH) formulation enables us to simulate viscoelastic tissue-mimicking materials. TLSPH is an extension of the conventional SPH method, which is often proposed for simulation of tensile instability processes and, hence, for simulation of solid materials undergoing large deformations. We obtain the properties of the soft tissue materials from the basic hereditary integral formulation and the generalized Maxwell model for finite-strain viscoelasticity theory, allowing for a combination of viscoelasticity and hyper-elasticity. Given the complexity of soft tissue material properties, an efficient continuum damage model is considered to evaluate the damage degree of particles, together with the SPH method to capture the resulting discontinuous damage. This combination of methodologies allows for modelling of damage and failure behaviour of soft tissue surrounded by a liquid.

This SPH solver will be tested for several cases of bubble collapses attached to or detached from the soft tissue. Compared to other coupling approaches using different methods, the selected SPH approach is able to capture fluid and solid responses straightforward and simultaneously, naturally satisfying the momentum conservation and saving computational resources.

Key Words: XFEM, GFEM, deflated CG, multigrid, domain decomposition

The eXtended/Generalised Finite Element Method (XFEM/GFEM) has significantly contributed towards the increase of the level of automation and computational efficiency of crack propagation simulations. The method substantially reduces, or even eliminates, the need for re-meshing by employing Partition of Unity (PU) enrichment, which extends the Finite Element (FE) approximation space to include functions encompassing known features of the solution. In fracture mechanics, features such as discontinuities and singularities can be represented independently of the underlying mesh, offering significant computational advantages. However, for large scale three-dimensional problems, the most computationally demanding part of the process is the solution of the resulting linear system of equations, which is typically performed using iterative solvers, such as the Preconditioned Conjugate Gradient (PCG) method. The XFEM/GFEM is known to produce ill-conditioned matrices, which can significantly slow down convergence of such methods, while discontinuities can also negatively affect the performance of commonly used preconditioners, rendering the overall solution process inefficient.

In the present work, a preconditioner based on adapted deflation [1] is employed to accelerate the solution of linear systems resulting from the discretization of fracture mechanics problems with well-conditioned extended/generalized FEs [2]. A novel approach is proposed for the construction of the deflation space, where the space typically used for linear elasticity problems is enriched with additional vectors, accounting for the enrichment functions used, thus effectively removing low frequency components of the error. To further improve performance, deflation is combined, in a multiplicative way, with a block-Jacobi preconditioner, which removes high frequency components of the error as well as linear dependencies introduced by enrichment. The resulting scheme is tested on a series of non-planar crack propagation problems and compared to alternative linear solvers in terms of performance.

A Discontinuity-enriched Finite Element Method for Dynamic Brittle Fracture

Yuheng Yan[1*], Alejandro M. Aragón[2]

Key Words: Discontinuity-enriched Finite Element Method, Dynamic Fracture, Linear Elastic Fracture Mechanics, Discrete Time Integration, Crack Propagation

The finite element method (FEM) is the standard procedure for modeling dynamic fracture but requires finite element (FE) meshes fitting to cracks. The eXtended/Generalized finite element method (X/GFEM) [4] elegantly decouples the description of cracks from the FE discretization by enriching or enhancing the standard FEM space. Yet, X/GFEM suffers from issues that are inherent to the formulation, including lack of stability, the need for non-standard procedures for prescribing non-zero Dirichlet boundary conditions, and an intricate computer implementation.

As an alternative to X/GFEM, the Discontinuity-enriched Finite Element Method (DE-FEM) [1, 6, 3] was proposed recently to solve problems with both material interfaces and cracks with a unified formulation. By collocating enriched nodes directly along discontinuities, DE-FEM also decouples cracks from the background FE mesh while solving X/GFEM's aforementioned issues. Yet, DE-FEM has only been explored so far for stationary cracks under stationary loading. In this presentation we demonstrate DE-FEM to simulate dynamic brittle fracture. We study the method in combination with both Newmark's constant average acceleration method and Bathe's method [2], and we use a fracture propagation criterion based on stress intensity factors obtained by means of a dynamic interaction integral [5]. Results show DE-FEM is an alternative to X/GFEM for solving dynamic brittle fracture problems.

Key Words: GFEM; XFEM; Multiscale; Structural dynamics; Wave propagation; Global–local analysis

This presentation reports on a high-order multiscale Generalized Finite Element Method (GFEM) tailored for the solution of structural dynamics and wave propagation problems exhibiting fine-scale and/or localized solution features such as singularities and discontinuities [1]. The proposed method uses an explicit time-marching scheme together with a block-diagonal lumped mass matrix applicable to arbitrary patch approximation spaces and adopts shape functions computed numerically on the fly through the solution of local initial/boundary value problems. Numerical results in for problems exhibiting singularities in the spatial gradient show that the proposed GFEM can accurately capture relevant features of the response using structural-scale meshes that are much coarser than those required by Direct Generalized Finite Element Analyses (DGFEAs) of comparable accuracy. In addition, a detailed study of the critical time step size of the method is presented and compared against the one for DGFEA discretizations that provide similar levels of accuracy. It shows that the proposed method has considerably looser time step size restrictions than available DGFEAs.

Key Words: CutFEM, Laser Ablation, Nitsche's Method

In this work, a model of thermal ablation with application to multi-pulsed laser lithotripsy is presented. The approach is based on the one-sided Stefan-Signorini model for thermal ablation and the CutFEM discretization, described in Claus et al.[1]. The model relies on a level-set function to represent the moving interface between the solid phase and a fictitious gas phase (representing the ablated material). Consistent with a CutFEM approach, the interface geometry is allowed to be arbitrary with respect to a background finite-element mesh. Nitsche's method is adopted to impose the Signorini condition on the moving interface. A bound constraint is also imposed to deal with the thermal shocks that can arise during representative simulations of pulsed ablation with high-powered lasers. We report simulation results based on experiments for pulsed laser ablation of BegoStone samples in dry conditions. The model is calibrated against experimental measurements by adjusting the percentage of incoming laser energy absorbed at the surface of the stone sample. Model-based simulation results are validated against experimental observations for the crater depth, volume, and geometry as a function of laser pulse energy and duration. Our results illustrate how the spreading of the laser beam from the fiber tip is necessary to model in order to obtain a qualitative match with the experiments. In particular, the model-based simulations indicate that ablation saturates after a finite set of pulses.

Space-Time Enriched Finite Element Methods for Wave Propagation

Kieran Quaine[1,2*] **and Heiko Gimperlein**[1]

Key Words: Generalized Finite Elements; Space-Time Methods; Plane-Wave Enrichment; Wave Equation; Elastodynamics.

Generalized finite elements based on plane-wave enrichments have been shown since the late 1990s to significantly reduce the computational cost for the numerical approximation of wave propagation and scattering problems in the frequency domain [2]. The enrichment of the approximation space allows good approximation of highly oscillatory solutions even on coarse mesh grids whereas standard methods are limited by fine meshes and small time steps. Recently enriched methods have been extended to time-dependent problems, using time-independent enrichment functions [2, 4, 5]. They reduce the computational effort in space, provided tiny time steps are chosen. In this talk we discuss space-time enriched methods for transient wave propagation on coarse space-time meshes [3]. We present a finite element method based on discontinuous Galerkin approximation in time and continuous elements in space, with plane-wave enrichments in space and time. Numerical experiments compare this approach to standard (polynomial-based) Trefftz methods [1] and to enriched methods based on time-independent enrichments [2]. For model problems in two-dimensions we demonstrate the significant reductions in the required computational effort and the rapid convergence of the proposed method on a fixed space-time mesh. We also discuss the influence of high condition numbers on the numerical solution, as well as the straight-forward extension to elastodynamics.

Time-dependent modelling of quasi-brittle materials with a strong discontinuity approach

Saeed Mohammadzadeh Chianeh[1], **Daniel Dias-da-Costa**[1,*]

[1] School of Civil Engineering, The University of Sydney, Sydney, NSW 2006, Australia

Key Words: Time-dependent behaviour, Discrete Crack Approach, Finite Element Method, Coupled Algorithm

The time-dependent behaviour of quasi-brittle materials can have a significant effect on serviceability and ultimate failure. E.g., in the case of concrete structures, the presence of cracking can evolve, propagate and gradually widen over time, therefore significantly changing the stress state and expected structural response. The development of models that can account for the discrete nature of cracking whilst predicting time-dependent behaviour can be of interest to many practical applications. The discrete strong discontinuity approach (DSDA) has been validated as a reliable formulation for simulating the cracking phenomenon by directly embedding the traction-separation constitutive relation within finite elements, therefore enabling (or enriching) standard finite element models with the ability to capture cracks, where material can separate without the need for remeshing. This work presents a generalisation of the DSDA to account for the long-term behaviour of cracked quasi-brittle materials, more specifically creep and shrinkage. To this end, a rate-type creep is first applied through a number of kelvin units; the interactive behaviour of the resulting response from the Kelvin chain system, shrinkage, and discrete cracking is developed to obtain a suitable constitutive model for the discrete crack simulations. Finally, the formulation is deployed on a finite element code where the performance of the proposed model is assessed through representative numerical examples.

Key Words: Extended finite element method, Electrostatic field analysis, Laplace problem, Conformal mapping, Complex function, Newton-Raphson iteration

In this presentation, we propose an extended finite element method that can effectively analyze the edge effect of the parallel plates capacitor.

The enrichment function, which plays an important role in this method, is defined as a simple function in the virtual space using the conformal mapping. The gradient of the enrichment function is also defined in the virtual space using the complex velocity potential. The enrichment function and its gradient are mapped into the real space by inverse mapping and used for numerical integration.

It is also very difficult to perform this inverse mapping analytically. We have performed it numerically, using the domain decomposition into triangles and the Newton-Raphson iterative scheme for complex numbers.

The effectiveness of the proposed method is verified by numerical experiments. To quantitatively evaluate the accuracy, we use the L_2 error norm of the solution and its gradient. The proposed method shows smaller error norms than the classical finite element method for equivalent resolution meshes.

A Consistent Multiphase Flow Model with Incompressible SPH for 3D Bubble Rising Problems

Lijing Yang[1], **Wei Hu**[1], **Dan Negrut**[1]

[1] University of Wisconsin-Madison, Madison, WI 53706, USA
lyang296@wisc.edu, whu59@wisc.edu, negrut@wisc.edu

Key Words: Multiphase flows, Smoothed particle hydrodynamics, Inompressible SPH, GPU computing, Particle shifting

A multiphase flow solution method developed with the incompressible smoothed particle hydrodynamics (SPH) method is outlined in this contribution. We will present a generalized particle shifting method for multiphase flows that maintains particle regularity, prevents interface particle mixture, and only introduces minimal perturbation to momentum conservation and system energy. The aforementioned generalized particle shifting method has been improved from the original method proposed in [1], and has demonstrated better solution accuracy and higher efficiency compared to the original method and the optimized particle shifting method [2], respectively. A color-function-based repulsive force will also be introduced in the presentation, which regulates the magnitude of repulsive force by the color function and effectively improves the interface smoothness especially for multiphase flows with high density ratios.

This solution approach employs consistent discretizations for the gradient and Laplacian operators, which enhances the accuracy of the spatial differential operators. The surface tension model embraced relies on the continuum surface stress (CSS) formulation. The solution methodology proposed is broadly applicable and the solution robustness can be preserved with density ratios up to 1:1000, and viscosity ratios up to 1:100. Numerical results for a series of benchmark problems will be presented to demonstrate the accuracy of the proposed model by comparing simulation results against analytical solutions, results from other numerical methods, and experimental data. The simulation of 3D bubble rising problems raises challenges on computational efficiency [3]. The proposed model has been implemented on GPU, which enables its capability to solve complex physics phenomena encountered in 3D bubble rising and coalescence problems via simulations that include over one million SPH particles.

Key Words: *Particle method, high-order schemes, stability, droplet, free surface, surface tension*

The droplet flow in the air can be simplified to a free-surface flow when the gas velocity is not high. The Lagrangian particle method is suitable for such flows. Nevertheless, the accurate and stable implementation of surface tension at free surfaces is still challenging. Recently, Matsunaga *et al*. [1] demonstrated that surface tension can be considered as a boundary condition at free surfaces based on a moving surface mesh. However, the surface mesh made it complicated and difficult to extend the method to 3D and simulate topological changes of interfaces. The aim of this study is to develop an accurate and stable particle method in 3D for droplet dynamics via replacing the surface mesh by the detected free-surface particles.

The surface tension is considered as a Dirichlet pressure boundary condition at free surfaces [1]. To enhance accuracy, the ***high-order schemes*** in our previous study [2] are employed instead of the ***conventional conservative schemes***. When the free surface particles are directly used, there are two well-known challenging problems: (a) the *instability* due to the mistaken free-surface detection [1, 2] and (b) the *fluctuation* of the detected free-surface boundary. To solve the first problem, the mechanism how the mistaken free-surface detection triggers fast error growth (i.e., instability) is analyzed theoretically and numerically. It is found that the summation of the discretization-model coefficients is closely related with the instability. Thus, *novel indices based on the discretization-model coefficients* are proposed for free-surface detection to suppress the instability. For the second problem, a new *surface-normal particle shifting* (SNPS) technique is proposed to alleviate the fluctuation of the detected free-surface boundary. Specifically, a smooth free-surface boundary is reconstructed based on the curve fitting method. Then the free-surface particles are gradually shifted to the reconstructed boundary. Based on these techniques, the stability of high-order schemes can be greatly enhanced for droplet dynamics with free surfaces.

Various numerical examples verified/validated the methods and demonstrated the improvements. The hydrostatic pressure and dam break problems demonstrated that the proposed indices detected fewer free-surface particles but produced better stability. The droplet deformation, coalescence, and breakup cases in 3D verified the method and demonstrated that the SNPS could greatly reduce the fluctuations and improve the accuracy. Briefly, it is well known that ***the high-order schemes*** suffer from ***instability*** easily ***at free surfaces***. The ***proposed techniques*** can effectively ***suppress the instability problem***.

Key Words: *Polygon Boundary, Ghost Particles, Machine Learning (ML), Moving Particle Semi-implicit (MPS)*

Solid boundaries are omnipresent in fluid simulations. Their accurate treatment remains an open and challenging topic for particle-based methods such as the Moving-Particle Semi-implicit (MPS). The main issue stems from the incompleteness of the kernel function near solid boundaries. The most common technique to handle this deficiency is using a set of ghost or fictitious particles, which help compensate for the kernel truncation. These particles can be pre-determined or dynamically positioned during simulation. They also help in producing the boundary forces and assigning boundary conditions. Nevertheless, even for two-dimensional models, this process can quickly become a bottleneck for particle methods when the wall geometry is complex (e.g., terrain) or moving.

The present study proposes a novel technique enabled by a Machine Learning (ML) approach that properly treats solid boundaries in fluid numerical simulation. Conventional ghost boundary particles are replaced with a fictitious polygon that encapsulates the behavior of all ghost particles. To achieve this with the help of an ML technique, a training data set for various boundary shapes are generated from simulations using the dynamic ghost particle method. The features of the rendered ghost particles are recorded, such as formation, solid-fluid interface, trimmed effective area, particles resolution, and particle number density. Symbolic states are specified and tagged manually. The label on each class describes how to mitigate kernel incompleteness according to its category. The saved data then serves to train a multiclass classification model. Once the ML model is trained, it estimates required boundary impact parameters (e.g., particle number density) on polygon represented boundaries (without ghost particles). The simulation results demonstrate the effectiveness of the new ML-accelerated technique in increasing the computational efficiency while maintaining the accuracy as equal to the standard ghost particle method, especially near sharp boundary edges.

Least Squares Based Particle Method for Accurate Free-surface Flow Simulation

Key Words: *Computational Fluid Dynamics, Incompressible Flow, Surface Tension, Meshfree Particle Method, Polynomial Reconstruction*

Meshfree particle methods, such as the SPH and MPS methods, have been attracting a great deal of attention, particularly in the engineering field, due to their high versatility for complicated physical problems including free-surface flow. However, the accuracy of these conventional particle methods is in general much lower than that of the prevalent grid-based methods. On the other hand, the least squares moving particle semi-implicit (LSMPS) method proposed by Tami and Koshizuka [1] is featured by an arbitrary high order accuracy. Nevertheless, the LSMPS method tends to be numerically unstable in the presence of large free-surface deformations. For these reasons, an accurate simulation of free-surface flow has been remained as a great challenge for meshfree particle methods.

Aiming at accurately and stably simulating a free-surface flow, we have developed two novel particle methods based on least squares. One of them is the moving surface mesh particle method [1], in which a moving surface mesh is incorporated to improve the treatment of free-surface boundary. The 2nd-order LSMPS scheme is adopted as the spatial discretization scheme. The numerical stability is effectively improved because of the use of the moving surface mesh. Highly accurate solutions have been obtained for surface tension dominant flows, such as droplet oscillation, dripping faucet, and continuous inkjet. However, the application of this method is limited to problems without complex topological changes such as the generation of splashes.

Another new particle method we have developed is a stabilized LSMPS method which is aimed at the accurate simulation of complex free-surface flow. In order to improve the numerical stability in the vicinity of the free surface, calculation algorithms for handling free surfaces and splashes are overall modified, where the surface fitting technique is incorporated to accurately and robustly estimate the normal vector to the free surface. Furthermore, the LSMPS scheme is extended by incorporating additional techniques (namely, Tikhonov regularization, diffuse derivative constraint, and linear equality constraint) to stabilize the spatial discretization. The proposed method has been applied to several benchmark problems, and consequently, the high accuracy is demonstrated for problems with free-surface deformations of moderate to high complexity.

MPS for modeling of multiphase granular flows: capabilities and limitation

Mojtaba Jandaghian[1], Herman Musumari Siaben[2] and Ahmad Shakibaeinia[3]*

[1]Polytechnique Montreal. mojtaba.jandaghian@polymtl.ca
[2]Polytechnique Montreal. herman.musumari-siaben@polymtl.ca

Key Words: Multiphase granular flow, Particle methods, Continuum-based modeling, MPS method, Multi-resolution model

Continuum-based particle methods, such as moving particle semi-implicit (MPS), provide the opportunity to simulate the multiphase granular flows with more accuracy and flexibility than the Eulerian mesh-based methods, and better computational efficiency than the discrete-based particle methods. Here we investigate the capabilities and limitations of these continuum-based particle methods for the gravity-driven and fluid-driven multiphase granular flows with different regimes (i.e. quasi-static, dense flow, and kinetic regimes). The model of this study is based on a multi-resolution, weakly-compressible moving particle semi-implicit (WC-MPS) with various stability and accuracy enhancement techniques. It used a generalized rheological model, using a regularized visco-inertial rheology that can describe the granular behavior in all regimes of multiphase granular flow. The result of the model is evaluated for the gravity-driven case of immersed granular collapse/slide, and the fluid-driven case of dam-break over an erodible bed, in comparison to the experimental data and discrete element method (DEM) results.

The results demonstrate the ability of the models in dealing with the large deformations in granular flows. A high sensitivity of results to the tensile instability (in high-shear regions) and unphysical fluctuations is observed. The enhancement techniques prove to be effective in improving the failure and post-failure behaviors of granular materials. The grain to particle size ratio is found to be a crucial factor in the accuracy of granular simulations. The multi-resolution technique shows to be effective and essential to keep the spatial resolution of the granular phase large enough for satisfying the continuum assumption, without scarifying the resolution and accuracy of the model for the fluid phase.

Surface Tension and Negative Pressure Calculation using Moving Particle Hydrodynamic Method

Key Words: *Particle methods, Surface tension, Wettability, Negative pressure, MPS, SPH, MPH*

Particle methods can calculate free surface flows without explicit surface tracking, and surface tension is of importance in properly capturing the surface motion especially in small scale problems. However, the surface tension calculation in particle methods has intrinsic difficulty because the tension in particle methods often results in strange agglomeration, which is called tensile instability. This instability also emerges in negative pressure calculations. To overcome this difficulty, the potential force which is long-range attractive and short-range repulsive is applied in some surface tension models [1-3]. It is expected that such potential based surface tension models are also useful in calculating the negative pressure. In this study, the potential based surface tension model [3] are diverted for negative pressure calculations (Fig.1) and their performance is studied using moving particle hydrodynamics (MPH). The pressure is directly evaluated with the interaction force via the virial theorem standing on the physical consistency of the discrete formulation in the MPH method.

Key Words: Defeaturing, trimming, geometric simplification, adaptivity

Defeaturing consists in simplifying geometrical models by removing the geometrical features that are not relevant for simulation. For instance, in solid mechanics simulations, they can be holes or fillets away from stress concentration regions. Simplifying the geometry of a computer aided design (CAD) model by defeaturing enables more efficient simulations for engineering analysis problems: the resulting mesh is simpler, the computation faster, and less memory storage is needed. However, the effects of defeaturing on the accuracy of the analysis are often neglected: it is a time-consuming task that is often performed manually and based on the expertise of engineers. Understanding well the effects of this process is an important step to be able to adaptively integrate design and analysis for CAD/CAE.

In this talk, we will formalize the process of defeaturing by understanding its effect on the solution of partial differential problems defined on the geometrical model of interest. More specifically, we have developed an *a posteriori* estimator of the energy error between the solutions of the exact and the defeatured geometries, that allows us to control the error made by adding or removing geometrical features. To this estimator, we have also integrated the numerical error due to the numerical approximation of the problem at hand when using hierarchical B-spline based isogeometric analysis on trimmed geometries.

The dependence of the estimator upon the size of the features and of the mesh elements is explicit, and the effectivity index is independent from the number of features considered. The estimator is proven to be reliable, it can be computed very efficiently, and it is naturally parallelizable with respect to the number of features. Finally, we propose a refinement strategy based on the estimator. It adaptively determines the mesh elements to refine, and chooses the features that are needed in the geometrical model, in order to achieve a certain precision.

Key Words: Isogeometric analysis, B-splines, smooth splines, quadrilateral meshes, hexahedral meshes.

Easy to construct and optimally convergent generalisations of B-splines to unstructured meshes are essential for the application of isogeometric analysis to domains with non-trivial topologies. Nonetheless, especially for hexahedral meshes, the construction of smooth and optimally convergent isogeometric analysis basis functions is still an open question. We introduce a simple partition of unity construction that yields smooth blended B-splines, referred to as SB-splines, on unstructured quadrilateral and hexahedral meshes [1]. To this end, we first define the mixed smoothness B-splines that are C^0 continuous in the unstructured regions of the mesh but have higher smoothness everywhere else. Subsequently, the SB-splines are obtained by smoothly blending the mixed smoothness B-splines with Bernstein bases of equal degree. One of the key novelties of our approach is that the required smooth weight functions are assembled from the available smooth B-splines on the unstructured mesh. The SB-splines are globally smooth, non-negative, have no breakpoints within the elements and reduce to conventional B-splines away from the unstructured regions of the mesh. Although we consider only quadratic mixed smoothness B-splines, the construction carries over to arbitrary degrees. We demonstrate the excellent performance and optimal convergence of SB-splines studying Poisson and biharmonic problems.

Key Words: Isogeometric Analysis, analysis-suitable T-splines, multivariate T-splines

T-splines were introduced in 2003 in computer-aided design as a new realization for B-splines on non-uniform meshes with local mesh refinement, and they were soon applied in the context of Isogeometric Analysis as ansatz functions for Galerkin schemes, however linear dependencies might occur in rare cases. In 2012, it was shown that linear independence is guaranteed if T-junction extensions do not intersect in different directions [1]. This criterion is called *analysis-suitability* and is equivalent to *dual-compatibility* [2], which states the existence of a dual basis that is constructable via local knot vectors. Analysis-suitability was generalized to bivariate T-splines of arbitrary polynomial degree [3], and, in an abstract version, to multivariate T-splines of odd degree [4].

In this contribution, we give a dimension-independent definition of analysis-suitable T-splines of arbitrary degree, including even and mixed degrees. We generalize both approaches to analysis-suitability, the abstract and the geometric one, and argue that both are sufficient for linear independence of the corresponding T-splines.

Key Words: Multi-patch C^1 spline spaces, hierarchical splines, isogeometric analysis

In recent years there is a considerable development of locally refinable spline spaces, due to their application to create adaptive algorithms for modelling, approximation and analysis. In particular, in Isogeometric Analysis (IgA), it was proved that using hierarchical splines leads to efficient methods for the solution of PDEs with optimal convergence rates (see, e.g., [1] for an overview). Moreover, combining IgA with C^1 spline spaces defined on multi-patch domains is a natural way to handle high-order problems on complex geometries. Therefore, there is the need for such kind of spaces which at the same time allow local refinement. Our approach combines recent techniques for the construction of C^1 tensor-product spaces (see, e.g., [3, 4]) with a new hierarchical framework (having relaxed assumptions with respect to the standard one). In this way, and by employing the results available for the two-patch case [2], we are able to obtain the desired locally refinable C^1 continuous spline spaces defined on multi-patch geometries.

Key Words: Loop subdivision, Isogeometric analysis, Optimal convergence rates, Nitsches technique

This paper introduces a modified version of Loop subdivision, called modified Loop subdivision surface (MLSS), to achieve optimal convergence rates in isogeometric analysis. Two main ideas are introduced to define MLSS. Motivated by the open knots for B-splines, we add a new layer of basis functions for the boundary of control grid, which can be evaluated similarly as that for Loop subdivision basis functions. This idea is used to solve the non-optimal convergence rates problem for extended Loop subdivision even without extraordinary points (EPs). For the EPs, we define a new rule with a parameter $\lambda(0 < \lambda < 1)$, which is exactly the second maximum eigenvalue of the subdivision matrix. The MLSS is defined by combining the two ideas, which is global C^2-continuous except G^1 and curvature bounded around the EPs. The MLSS limit surface has comparable shape quality as Loop subdivision surface. Besides that, the numerical experiments show that MLSS can achieve optimal convergence rates in the Poisson problem both in the L_2 and H_1 norm.

Key Words: *Isogeometric analysis, Kirchhoff-Love shell, TCB-splines, extraordinary points*

This paper presents the application of TCB-splines for representing and analyzing the Kirchhoff-Love shell in the context of isogeometric analysis (IGA). The Kirchhoff-Love shell formulation requires globally C^1-continuous basis functions. The nonuniform rational B-spline (NURBS)-based IGA has been extensively used for developing Kirchhoff-Love shell elements. However, shells of complex geometries inevitably need multiple patches, where stitching patches with high continuity is a challenge. On the other hand, due to their unstructured nature, TCB-splines can accommodate general polygonal domains and are flexible to model complex geometries with C^1 continuity, which naturally fit in the Kirchhoff-Love shell formulation with complex geometries. We propose to use TCB-splines as basis functions for both geometric representation and solution approximation. We apply our method on shell benchmark problems, where optimal convergence rates are achieved. The applicability of the proposed approach to shell analysis is further exemplified by performing geometrically nonlinear Kirchhoff–Love shell simulations of an oil sump of a car and a pipe junction represented by a single patch of TCB-splines free of extraordinary points.

Stabilized Overlapping Multi-patch Isogeometric Formulation of the Stokes Problem

[4] Institute of Mathematics, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, xiaodong.wei@epfl.ch

Key Words: *Stabilized Method, Overlapping Patches, Trimming, Union, Stokes Problem, Isogeometric Analysis*

We present a novel stabilized isogeometric formulation for the Stokes problem, where the geometry of interest is obtained in the means of overlapping NURBS (non-uniform rational B-spline) patches, i.e., one patch on top of another in an arbitrary but predefined hierarchical order. All the *visible* regions constitute the computational domain, whereas independent patches are coupled through visible interfaces using Nitsche's formulation. Such a geometric representation necessarily involves trimming, which, however, may yield trimmed elements of extremely small measures (referred to as *bad elements*) and thus lead to the instability issue. Motivated by the *minimal stabilization* method that rigorously guarantees stability in problems using trimmed geometries [1, 2], in this work we generalize it to the Stokes problem on overlapping patches. Central to our method is the distinct treatment for pressure and velocity spaces, where stabilization for velocity is carried out for the flux terms on interfaces, whereas pressure is stabilized in all the bad elements. We provide a priori error estimates with a comprehensive theoretical study. Through a suite of numerical tests (particularly with two-dimensional Taylor-Hood elements), we first show that optimal convergence rates are achieved, which consistently agree with our theoretical findings. Second, we show that the accuracy of pressure is significantly improved up to several orders using the proposed stabilization method, compared to the results without using stabilization. Finally, we also demonstrate the efficacy and efficiency of the proposed method in an advection-dominated problem, i.e., the Oseen problem.

A Radial Basis Function Partition of Unity Method for Thin Structures

Elisabeth Larsson[1*], Pierre-Frederic Villard[2], Igor Tominec[1], Ulrika Sundin[1], Andreas Michael[1], Boštjan Mavrič[1], and Nicola Cacciani[3]

[3] Karolinska Institutet, SE-171 77 Stockholm, Sweden, nicola.cacciani@ki.se

Key Words: Radial basis function, partition of unity, anisotropic, unfitted, least squares

Computational modelling of thin structures is a challenging problem. If variations in the thin direction can be neglected, shell elements can be used to simplify the problem and to reduce the computational cost. However, if this is not the case, also the thin direction needs to be resolved. A uniform discretization, e.g., through meshing, leeds to a high computational cost, since the extent of the structure along the surface is large compared with the thickness. A global anisotropic discretization is difficult to construct and to work with if the structure does not have a parametric representation.

Meshfree methods provide flexibility with respect to geometry, but have similar limitations with respect to discretization of thin structures. In [1] an unfitted least-squares radial basis function partition of unity method (RBF-PUM) was derived. The main benefits of unfitted least squares RBF-PUM are that it is stable under node refinement, that node generation becomes trivial, and that it is computationally efficient due to its local support and the reusability of local computations.

We have formulated an adapted version of unfitted least squares RBF-PUM that is suitable for thin structures. An RBF-PUM discretization is based on local approximations in overlapping patches that are then blended together to form a global solution. Typically patches are uniformly distributed and equally sized cubes or spheres, but we instead use anisotropic patches in the form of cylinders that are aligned with the structure, such that the heights of the cylinders are similar to the thickness of the structure. Within each patch we can then control the local resolution of the thin direction by scaling the local problem. We show eaxmples where the method is used both for geometry reconstruction [3] and for linear elastic deformation [2].

Key Words: Linear elasticity, partition of unity, radial basis functions, 3D deformation

In this talk we will present numerical simulations of deformed 3D objects. The simulations are produced by numerically solving the linear elasticity equations on complex shell geometries. We use the meshless RBF based partition of unity (RBF-PUM) method in the least squares formulation [1] and this talk will focus on applications of this method on various geometries.

The method is used to both reconstruct the geometries and numerically solve the governing PDEs. It is mesh-free and it solves the PDE in its strong form, pointwise. Hence, it is particularly adept in solving PDEs on complex geometries where mesh generation is non-trivial and the resulting mesh can be highly anisotropic. It is also easy to implement, flexible and computationally efficient.

The continuum bodies simulated are linearly elastic. We specifically assume small strains, meaning the constitutive relation between stress and deformation is linear. We compute the deformations by numerically solving a system of linear PDEs arising from Cauchy's equation of equilibrium in elastostatics. The deformed geometries include the Stanford Bunny [2], a hollow 3D cube with complex webbing and a 3D reconstructed model of the human diaphragm [3].

We will present realistic deformations and stresses, computed using the von Mises yield criterion. Finally, we will show convergence studies for the least squares residual and a comparison with the Finite Element Method (FEM) which proves that this method produces comparably accurate results. In conclusion, we aim to showcase the versatility and robustness of this method, especially when solving PDEs on complex 3D geometries.

Discrete Conservation in Meshfree Collocation Methods for Fluid Flow

Pratik Suchde[1]

Key Words: *Meshfree, Lagrangian, Conservation, Particles*

Over the last few decades, meshfree or meshless methods have become a popular alternative to conventional mesh-based solution procedures, especially for fluid flow problems with time-dependent domains and rapidly changing free surfaces. They can be easily used in a Lagrangian framework, which enables them to easily model large deformations and displacements. However, these advantages naturally come with their own challenges. One of the biggest drawbacks of meshfree methods is the lack of discrete conservation.

In this talk, we present an overview of different aspects of conservation issues in collocation-based meshfree methods. First, we discuss the lack of formal conservative properties inherent in the derivative approximation procedure across most, if not all, "purely" meshfree methods. Central to this is the lack of a discrete Gauss theorem, and the absence of a natural way to define fluxes. We show that obtaining formal conservation in this setting necessitates a global computation of discrete differential operators, which makes the solution procedure very slow and not feasible for Lagrangian frameworks. To avoid this, we introduce a method of approximate flux conservation in meshfree methods.

While focusing on incompressible flow, we also present the issue of volume and mass conservation in Lagrangian meshfree frameworks. We then introduce a concept of representative masses in Lagrangian meshfree collocation methods that can reduce the impact of these issues. We further introduce a notion of mass transfer between collocation "particles" that ensures the notion of representative masses can also be used for complex flow problems with large deformations in the fluid domain. After a series of verification and validation test cases that highlight the impact of the introduced framework, we also present the application of the method to an industrial test case of automotive water crossing.

Key Words: Finite Difference Method, Radial Basis Functions, Polyharmonic Splines, Monomials, *h*-adaptivity, Linear Elasticity

In this research, an advanced finite difference (FD) scheme is constructed for the numerical solution of the partial differential equations (PDE) describing linear plane elasticity problems, which is based on the radial basis function technique (RBF). The widely-used RBFs are classified into two main groups, the infinitely- and the piecewise smooth RBFs [1]. The infinitely smooth RBFs depend on a shape parameter, setting the gradient of the RBFs and thereby controlling the condition number of the local RBF matrix, influencing the accuracy of the differentiation weights. However, the polyharmonic spline (PHS) as piecewise smooth RBF is independent of a shape parameter and its application can lead to higher convergence rates and more accurate results [1]. This is the reason why the PHS will be chosen for the computation of the weights. Furthermore, the PHS as RBF will be augmented with *p*-degree monomials for the sake of the achievement of faster convergence and increased accuracy.

An averaged residual-maxima based adaptive point-cloud refinement strategy will be presented and its computational performance will be tested on the convergence behavior of two kinds of benchmark problems: (i) smooth and (ii) non-smooth boundary value problems (BVP) (such as the shock- and the singular problem) [2, 3]. Since for these non-smooth BVPs, the *h*-adaptivity improves significantly the accuracy and the convergence rates, it would be worth extending the *h*-adaptive PHS-RBF FD method to 3D, time dependent and non-linear problems arising in solid mechanics.

Key Words: Discontinuous Diffusion, GFDM, Anisotropic Diffusion, Meshfree

Physical properties with jumps appear in numerous applications in continuum mechanics such as multiphase flow, composite materials or phase change. Our goal is to describe phase change processes in a monolithic model with a meshfree generalized finite difference method (GFDM). Phase change leads to formation of interfaces at which physical properties such as thermal conductivity, density and viscosity have jumps. Since these physical properties appear in diffusion operators, we pay special attention to the formulation of the diffusion operator.

Meshfree GFDM have successfully been used in free surface flows with complex geometries. However, difficulties arise with the diffusion operator, since the method has no efficient way to ensure conservation of physical properties at interfaces or diagonally dominant numerical operators. This issue can be observed especially at interfaces where the diffusion coefficient has a jump, possibly of several orders of magnitude. Typical solution procedures for anisotropic laplacians include domain decompositions. However, in phase change we cannot predict the position of the interface and more importantly the interface can be smeared out accross a transition region.

To overcome the drawbacks of the current formulation, we present a numerical method that identifies regions where the diffusion coefficient has large jumps. A hybrid approach is proposed that ensures better algebraic properties for the linear system in these critical regions. This method is benchmarked against several test cases with varying jump magnitudes and geometric complexities of the interfaces.

Parameter Identification by Deep Learning for subsequent MESHFREE Simulations of Granular Media

Derick Nganyu Tanyu[1*], Isabel Michel[2], Andreas Rademacher[1], Peter Maass[1], Jörg Kuhnert[2]

Key Words: *Parameter Identification, Meshfree method, Generalized Finite Difference Method (GFDM), Deep Learning, Inverse Problem, Model Reduction, Principal Component Analysis*

There are essentially two different paradigmatic approaches for mapping complex physical processes: classical physical modelling with associated numerical simulation (model-based) and prognostic methods based on the analysis of large amounts of data (data-driven). In recent years, the efficient combination of both approaches has become a research topic in its own right. However, research is far from an interlocking, problem-adapted application of these principles.

In the BMBF-project HYDAMO (Hybrid data-driven and model-based simulation of complex flow problems in the automotive industry), the interest is on the one hand in meshfree simulations of sand-like materials based on a model hierarchy with increasing complexity. The correct choice of parameters in the individual model stages is essential for the appropriate mapping of the processes. Furthermore, the development of an automated and efficiently calibrated prediction tool is necessary for industrial application. This is achieved by enhancements of the Generalized Finite Difference Method (GFDM) implemented in the MESHFREE software [1].

On the other hand, the project aims at reducing the high-dimensional parameters in a generic material model to their inherently nonlinear but low-dimensional structure by deep learning approaches and to identify them for the subsequent numerical simulation. As a step towards achieving this goal, data pairs generated from MESHFREE simulations (which solve the parametric partial differential equation (PDE) in a forward problem) are used to in turn apply deep learning methods for the parameter identification problem (inverse problem). Deep learning has recorded recent successes in solving parametric PDEs [2]. In this work, the method of interest here stems from the recent successes of deep learning, when combined with ideas from model reduction [3]. Here, stress over time constitutes the input, while the parameters of interest constitute the output. Both are reduced to some latent spaces by principal component analysis (PCA) and a neural network then maps these two latent spaces.

Key Words: Radial basis functions, RBF-FD, least squares, hyperelasticity, biomechanics

Despite the flexibility of the collocation RBF-FD method to describe complex geometries and the simplicity of its implementation, the method has failed to gain significant traction in the solid mechanics community. This is at least in part caused by the fact that the method in its simplest form fails to give stable solutions for problems including Neumann boundary conditions and different stabilization techniques need to be used to include traction boundary conditions in the models.

However, recent research shows that problems with the stability can be overcome by oversampling the governing equation and solving the problem in least-squares sense [1]. This also allowed for an unfitted method to be developed, making it even simpler to describe complex geometries [2].

This contribution applies these new findings to the problem of hyperelastic solid mechanics models found in biomechanics with the purpose of modeling the human diaphragm [3]. The solution procedure is presented and the implementation is verified by comparison to FEM models. We perform a parametric study of the free parameters that are introduced by the solution procedure and the different evaluation paths that are made possible by the introduction of least squares solution to the governing equation.

Stochastic flow simulation in 3D porous media, application the knee meniscus

Anas Obeidat[1*] **and Andreas Zilian**[1]

[1] University of Luxembourg, Department of Computational Engineering Sciences, Faculty of Science, Engineering and Communication, University of Luxembourg, , Avenue de la Fonte, 4364, Esch-sur-Alzette, Luxembourg. anas.obeidat@uni.lu

Key Words: Discretisation-Corrected Particle Strength Exchange, stochastic porous media, meniscus, data driven, homogenisation, Brinkman penalisation

Flow and transport computations for explicit microstructures of stochastic porous media, here the knee meniscus, are prohibitively time consuming. First, as the porous microstructure is geometrically complex, each simulation is considerably time consuming. Second, the porous microstructure is intrinsically stochastic as it varies from location to location and from specimen to specimen, requiring numerous time-consuming experiments and flow computations to be performed. First, we address the continuum biological hydrodynamics simulation in complex geometries, by presenting a novel integrated computational approach using the Discretisation-Corrected Particle Strength Exchange (DC PSE) [1] operator discretisation in a strong-form collocation mesh-less solver, the solver is coupled with Brinkman penalisation [2] to add a layer of robustness when dealing with such stochastic complex geometries. Steady and unsteady Navier-Stokes equations are solved using the solver. Then, we introduce a data driven framework in which the porous microstructures are homogenised to enable simulations in which the explicit microstructural representation is omitted, but the stochastic transport characteristics are preserved. Only a few meniscuses need to be characterised and a few sub- scale microstructural simulations on statistical volume elements are required to probabilistically identify the parameters of the random spatial fields of the permeability coefficient. The probabilistic identification setting assumes that each spatial input field is a realisation from a single, joint multi-dimensional probability density function. The probabilistic identification setting is based on Bayes' theorem, which only requires a limited number of measurements. Finally, we will use the identified probability density function to rapidly propagate the uncertainty with the fast homogenised model.

Key Words: *Water, Evaporation, Meshfree method, Generalized Finite Difference Method (GFDM), Finite Pointset Method (FPM), Lagrangian, CFD, Multiphase, Multiphysics problems, Mass-transfer*

The evaporation of water can be easily observed in daily life. Unlike its occurrence, however, it is not straightforward to accurately resolve the problem and to predict the evaporation rate. Evaporation is a rather complex multiphysics mass-transferring process at the free surface between two phases — water and air, where a number of factors play roles [1]. Nevertheless, it is crucial to accurately estimate the evaporation rate at the given conditions in many industrial fields such as the prediction of local corrosion effects in automotive applications. Therefore, a robust numerical method is required to resolve evaporation phenomena.
The Finite Pointset Method (FPM), a Generalized Finite Difference Method (GFDM) implemented in the software MESHFREE, is widely used in academic and industrial areas [2,3], especially in automotive water management applications. Its efficiency is based on the meshfree character that eliminates the often-time-consuming process of meshing and re-meshing in other methods.
A mass transfer model is implemented in MESHFREE in order to simulate the free water surface evaporation phenomenon at the water-air interface. Thereby, it is assumed that the main driving force of the liquid mass transfer into vapour is diffusion driven by the vapour concentration gradient in the air phase close to the free water surface [4]. To resolve the vapour concentration gradient along the interface normal direction adequately, coupled two-phase simulations were executed. Hence, the simulation can also take into account the effects of forced convection and relative humidity in air phase, which are necessary to correctly predict the evaporation rate.
The simulation results are validated based on a series of experiments that measure the water evaporation rate with a relatively simple geometry. In the experiments, controllable conditions that highly influence the evaporation rate including air temperature, relative humidity and air flow rate are varied. The measured evaporation rates are then compared with the results from multiphase MESHFREE simulation with the newly implemented evaporation model.

Key Words: *Physics-Informed Neural Networks, Deep Learning, Data-Driven Science*

Due to global warming and climate change, a number of natural disasters have been occurring in various places (e.g., the 2011 Tohoku earthquake and tsunami and the 2017 Northern Kyushu floods), raising the demand for predictive simulation technology. To perform numerical simulations, material parameters need to be determined, however, they depend on empirical laws and hence, their application ranges remain vague.

In this context, this work presents the application of Physics-Informed Neural Networks (PINNs) [1] to inverse problems of fluid flow. The characteristic of PINNs is that the network output is constrained to satisfy the informed physical laws, initial, or boundary conditions. This is achieved by forming the loss function as a linear combination of a supervised loss of data measurements and an unsupervised loss of governing equations by automatic differentiation [2] (Navier–Stokes equations in the presented study):

$$\mathcal{L} = w_{\text{data}}\mathcal{L}_{\text{data}} + w_{\text{PDE}}\mathcal{L}_{\text{PDE}} \tag{1}$$

$$\mathcal{L}_{\text{data}} = \frac{1}{N_{\text{data}}}\sum_{i}^{N_{\text{data}}} (\mathbf{u}_i - \hat{\mathbf{u}}_i)^2 + (p_i - \hat{p}_i)^2 \tag{2}$$

$$\mathcal{L}_{\text{PDE}} = \frac{1}{N_{\text{PDE}}}\sum_{i}^{N_{\text{PDE}}} (\nabla \cdot \hat{\mathbf{u}}_i)^2 + \left(\frac{D\hat{\mathbf{u}}_i}{Dt} + \frac{1}{\hat{\rho}}\nabla\hat{p}_i - \hat{\nu}\hat{\mathbf{u}}_i\right)^2 \tag{3}$$

Here, $\mathbf{u}_i$ and p_i are training data for velocity vector and pressure, $\hat{\mathbf{u}}_i = \hat{\mathbf{u}}(\mathbf{x}_i, t_i)$ and $\hat{p}_i = \hat{p}(\mathbf{x}_i, t_i)$ are PINNs-predicted velocity and pressure, respectively. $\hat{\rho}$ and $\hat{\nu}$ are identified density and kinematic viscosity of the fluid. Original work of PINNs [1] has investigated its applicability to slightly corrupted training data (1% noise), however, the data should have stronger noise in real-world applications. This work specifically considers its performance for inverse problems when the data includes 20% noise [3]. It further studies an approach to correctly estimate the unknown parameters ($\hat{\rho}$ and $\hat{\nu}$) by varying the weights to each of the loss terms and discusses PINNs applicability to considerably noisy training data.

Key Words: *Isogeometric Analysis, Collocation, Galerkin; Newmark methods; absorbing boundary conditions, acoustic waves.*

Isogeometric collocation methods combine the high smoothness of NURBS basis functions with the low computational cost of collocation methods, generating sparser stiffness and mass matrices than the ones generated by isogeometric Galerkin methods. Our previous work investigated the approximation of 2D acoustic wave problems with proper absorbing boundary conditions by Galerkin IGA methods in space and Newmark's explicit schemes in time (IGA-Gal-New). In this talk, we extend our study to IGA collocation explicit and implicit approximations (IGA-Col-New). A detailed numerical study on both Cartesian and NURBS domains illustrate the stability and convergence properties of the two Isogeometric Newmark methods with respect to the IGA and Newmark discretization's parameters. The experimental results show that the stability thresholds of the methods depend linearly on h and inversely on p, confirming that the proposed IGA-Col-New method retains the good convergence and stability properties of standard IGA-Gal-New and Spectral Element discretizations of acoustic problems.
Moreover, a detailed comparison of convergence errors, CPU time, and matrix sparsity patterns show that IGA-Col-New often outperforms IGA-Gal-New, in particular in the case of maximal regularity $k = p - 1$ and for increasing NURBS degree p. Some numerical results on the spectral properties of the IGA-Col-New matrices are also mentioned.

Key Words: Isogeometric Analysis, IETI, Mortaring

In the simulation of real world problems using isogeometric analysis one challenge that often arises is the treatment of geometries with nonconforming discretizations of patches. One way to deal with these geometries is to make the patches conforming. This can be done manually or using suitable trivariate CAD software. However, for complex geometries it is not always possible to ensure compatibility of all trivariate patches at interfaces. In this case, a mortar method [1, 3] can be used to carry out simulation on nonconforming patches.

We present a workflow for the simulation of problems on 3D geometries with nonconforming geometry discretizations based on mortaring and IsogEometric Tearing and Interconnecting (IETI) method implemented in IRIT [2] and GeoPDEs [4]. For this method, we only require a pairwise matching discretization on the 2D interface of two neighboring patches for the numerical quadrature.

sonnen@ipp.mpg.de

Key Words: toroidal domains, polar splines, conforming/non-conforming Finite Element methods

We present a discretization of the continuous de Rham complex by means of adequate spline spaces sustaining the same cohomological structure, when the underlying physical domain is a toroidal solid. Discretizations preserving such homological invariant of the physical model are commonly exploited in electromagnetics to obtain numerical solutions satisfying important conservation laws at the discrete level. Thereby one avoids spurious behaviors and, on the contrary, improves accuracy and stability.

The toroidal geometries are of particular interest, for example, in the context of magnetically confined plasma simulations. The singularity of the parametrization of such physical domains demands the construction of suitable restricted spline spaces, called polar spline spaces, ensuring an acceptable smoothness to set up the discrete complex.

On the other hand, the polar structure of the basis functions is not compatible with parallel computing when adopting MPI algorithms, at least near the singularity. Whereas the tensor structure would easily accomplish the task. Therefore, in order to obtain a discretization capable to scale well with problems of large dimensions, we further present a, so called, conforming/non-conforming (CONGA) variation of the method. In this approach, the approximation is built in the ambient space of the tensor splines, which easily allows a parallelization of the processes, and then projected on the polar spline subspace to preserve the conformity of the discretization.

Design-related Simulation – A Discussion

Uwe Schramm
Altair Engineering, schramm@altair.com, www.altair.com

Key Words: *Design-related simulation, Meshless finite elements, Topology optimization.*

The spread of simulation has changed the way how highly engineered products are designed. Finite element simulation made user friendly thru effective modeling software is the dominant technology for simulation. The introduction of optimization associated with finite element methods, especially generative design or topology optimization has transformed simulation into a design tool and moved simulation way up into the concept phase of design processes.

However, in many industries designer and analyst are separate functions. Management always wants designers to do analysis and simulation too. Skill levels are just different, and tools are not available to cater to a community that does not have the skill to make necessary assumptions that are needed to model complex events and systems with traditional means. Many attempts to create a simplified user experience to entice designers to adopt more simulation in their daily work did not change that. To a certain extend topology optimization packaged in an easy-to-learn user experience provided some part-level simulation capabilities to answer designer's simulation needs.

We will introduce a software solution that addresses the limitations above. This technology is completely meshless and works directly on CAD geometry. It can deal with assemblies and complex part connections in an easy way. Simplifications common in traditional mesh-based finite element methods (rigid elements for connections, thermal loads for bolt pretension, etc.) that require expert knowledge are not necessary. The software deals with the physics directly. Even the complicated task of figuring out boundary conditions for a part analysis becomes easy as complete assemblies can be dealt with.

We will discuss how this technology is going to change simulation processes. We will review the entire process chain of designing complex products, including the role of generative design, and how it interacts with design-related simulation.

Efficient Numerical Integration for Trimmed Isogeometric Analysis based on Error Correction

Felix Scholz[1*], **Bert Jüttler**[2]

Key Words: isogeometric analysis, trimming, numerical integration, fictitious domain methods

The numerical integration on domains that are cut by an implicitly defined boundary curve or surface is an important problem that arises when solving partial differential equations on trimmed computational domains using isogeometric analysis or unfitted finite element methods. Since the assembly of the system matrices can be a bottleneck for the overall computation, efficient methods for the numerical integration are needed. At the same time, in order to guarantee optimal convergence orders, the method for numerical integration needs to achieve an approximation order that is equivalent to the approximation order of the employed discrete space.

In this talk, we present a method for the numerical integration on trimmed computational domains that is based on a local error correction approach. In each cut integration cell, we first find a linear approximation to the trimming boundary. Then, we increase the approximation order by adding correction terms based on a Taylor expansion. The computational complexity of the resulting method is equivalent to the complexity of a standard element-wise Gaussian quadrature on a non-trimmed domain.

In [1] and [2], we showed that the first order correction term results in a a fourth-order convergence rate in each cut integration cell and is therefore suited for isogeometric analysis with quadratic splines on both bivariate and trivariate domains. We generalized the method to obtain arbitrary approximation orders for numerical integration on trimmed planar domains in [3]. The method can therefore be used for high-order isogeometric analysis and for high-order unfitted finite element methods.

Electromagnetic wave propagation through structure-preserving spline differential forms

B. Kapidani[1] and Rafael Vázquez[1*]

[1] Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland,
{bernard.kapidani;rafael.vazquez}@epfl.ch

Key Words: Splines, Maxwell, Dual mesh, Hodge operator

A new *structure-preserving* numerical method will be presented which exhibits high order convergence and, contrarily to other high order geometric methods [1], does not rely on the geometric realization of any dual mesh. We use B-spline based de Rham complexes [2] to construct two exact sequences of discrete differential forms: the primal sequence $\{X_h^k\}$ starts from the space of tensor-product splines of degree p and at least C^1 continuity. The other spaces of the primal sequence are built by suitable tensor-product of splines of mixed degree p and $p-1$. Similarly, the dual sequence $\{\tilde{X}_h^k\}$ starts from the space of tensor-product splines of degree $p-1$, which in the parametric domain coincides with the last space of the primal sequence. The construction of the other spaces of the sequence follows an in the primal one, by using splines of mixed degrees $p-1$ and $p-2$.

The differential operators (gradient, curl and divergence) are comprised in the exterior derivative operator. Due to the high continuity of splines, the exterior derivative is well defined both for the primal and the dual sequence. Moreover, assuming vanishing boundary conditions on the primal sequence, the discrete spaces X_h^k and $\tilde{X}_h^{3-k}$ have equal dimension.

The method is completed with two sets of discrete Hodge–star operators, that relate the spaces of the two sequences, mapping the space of primal forms X_h^k into the space of dual forms $\tilde{X}_h^{3-k}$, and vice versa, for $k = 0,1,2,3$. The discrete Hodge–star operators encapsulate all the metric-dependent properties, including material properties. We will show a particular choice of the discrete Hodge–star operators inspired by [3] and how to compute them through the fast inversion of Kronecker product matrices. Finally, we will apply the method to the solution of Maxwell equations, and show that the method exhibits high order convergence and energy conservation.

Key Words: Isogeometric Analysis, Spline Approximation

Splines are piecewise polynomial functions that are glued together with a given smoothness. When using them in a numerical method, the availability of proper error estimates is of utmost importance. Classical error estimates for spline approximation are expressed in terms of (a) a certain power of the maximal grid spacing, (b) an appropriate derivative of the function to be approximated, and (c) a "constant" which is independent of the previous quantities but usually depends on the degree and smoothness of the spline.

An explicit expression of the constant in (c) is not always available in the literature, because it is a minor issue in most standard approximation analysis. There they are mainly interested in the approximation power of a spline space of fixed degree. However, one of the most interesting features in the field of Isogeometric Analysis is k-refinement, which denotes degree elevation with increasing interelement smoothness. The above mentioned error estimates are not sufficient to explain the benefits of approximation under k-refinement so long as it is not well understood how the constant in (c) behaves.

In this talk we extend the results of [1] by providing a priori error estimates with explicit constants for both the L^2-projection and Ritz-type projections onto spline spaces of arbitrary smoothness defined on arbitrary grids [2]. The presented error estimates indicate that smoother spline spaces exhibit better approximation per degree of freedom, even for low regularity of the function to be approximated. This is in complete agreement with the numerical evidence found in the literature.

We further discuss the extension of these results to the case of tensor product spline approximation and to isogeometric spline spaces generated by means of a mapped geometry, both in the single-patch and in the multi-patch case.

Key Words: Isogeometric Analysis, Shape Morphing, Maxwell's Eigenproblem

In our work, we are investigating the Maxwell Eigenproblem in accelerator cavities whose performance is evaluated based on their eigenmodes. For cylindrical cavities, the eigenfrequencies and electromagnetic field distributions are known analytically and a well-known nomenclature is defined for classifying the modes. Due to the complex shape of real-world cavities, in practice the eigenmodes need to be determined using numerical simulations. Hence, also the classification of their eigenmodes is cumbersome.

Therefore, we investigate automatic mode recognition by deforming the cavity geometry to the cylindrical shape. To this end, an eigenvalue tracking technique is employed to ensure consistency of the solution along the deformation of the cavity geometry, i.e. to match the eigenpairs. Since crossings of the eigenvalues can occur along the deformation, sophisticated methods are necessary. Finally, the numerical results are aligned with the analytic solutions.

Employing Isogeometric Analysis (IGA) for the spacial discretization of the cavity allows for an exact representation of the geometry and smooth fields for subsequent particle tracking. Furthermore, describing the deformation of the geometry with IGA is straightforward and does not require remeshing along the shape morphing. In our work, we apply algorithms, which employ derivatives with respect to an introduced deformation parameter, to track the eigenvalues along the deformation. We formulate the required derivatives of the system matrices as shape derivatives with respect to the IGA control points.

[2] Iowa State University, Ames, IA, USA
[3] University of Colorado Boulder, Boulder CO, USA

Key Words: Code generation, FEniCS, isogeometric analysis, immersogeometric analysis

Code generation for numerical partial differential equations (PDEs) lets users automatically compile efficient solver routines from mathematical problem descriptions. However, it typically assumes rigid code structures that are only immediately applicable to certain numerical methods, such as the finite element (FE) methods considered in the FEniCS [1] code generation system. Standard FE methods cannot be applied directly to PDE systems on geometries from typical computer aided design (CAD) systems; they also struggle with geometric complexity arising from nonlinear physical phenomena, e.g., extreme deformations, contact, or fracture. Numerical schemes to couple non-matching parameterizations of geometry or handle large deformations and topological changes cannot be directly implemented using FEniCS's standard code generation workflow. Thus, an active area of research is: How can advanced code generation capabilities be productively applied in such methods? The present talk will review how FEniCS has been extended to isogeometric analysis [2] and discuss a recent extension to shell analysis of aerospace structures defined using multiple non-matching spline patches [3]. We will also discuss advances in fluid–structure interaction (FSI) analysis using CAD-based descriptions of thin structures immersed in unfitted meshes, building on preliminary work from [4]. This will enable rapid prototyping of both constitutive and geometric modeling choices in the design and FSI analysis of prosthetic heart valves. Lastly, we will cover ongoing work toward leveraging code generation within a general-purpose framework for high-order immersed finite element and isogeometric methods. These various projects illustrate different promising approaches to the central research question identified above.

Key Words: *Isogeometric Analysis, 3D potential flow, Adaptive Refinement*

The authors have previously presented in [1] the development and benchmarking of an IsoGeometric Analysis Boundary Element Method (IGA-BEM) solver for the 3D flow around lifting wings with finite span, based on Morino's formulation for the perturbation potential [2]. The solver employs the same analysis-suitable T-spline basis for the representation of both wing's boundary surface and the unknown field quantities. The 3D character of the flow near the wing tip and the resulting flow velocity singularity at the intersection of the wing tip with the trailing edge entail the adoption of a local refinement process to improve the rate of convergence of the numerical solution of the problem.
In this work, we are focusing on the study of the accuracy and efficacy of the original IGA-BEM solver using both NURBS and T-splines representations for the body geometries. Specifically, we are interested in:

1) the efficacy and achievable accuracy of different global and local refinement strategies when evaluating the quantities of interest (pressure & lift). Our strategies include standard adaptive refinement schemes comparing successive refinement steps, and a simplified refinement approach which compares the values of the solution at neighboring collocation points and refines the corresponding knot intervals when differences are larger than a specified tolerance.
2) The efficacy and accuracy that can be achieved by optimizing the methods of integration and the number of quadrature points used in the calculation of integrals involved in the assembly of the matrix of the employed collocation scheme.

Results and comparisons employ both NURBS and T-Splines geometry representations.

Key Words: *Inverse Design, Shape Optimization, Production Engineering*

Without appropriate manufacturing processes, product innovations cannot be brought into our daily lives. As such, there is a constant need for innovative, flexible, and precise manufacturing processes. At the same time, the manufacturing process can act as a significant cost driver, in particular in the range of small lot sizes. These costs can be divided into two categories: One is the manufacturing step itself, which requires material and tailored machinery. The other category is the design of the manufacturing process, a preprocessing task that defines tool shapes, plans paths, etc.. This presentation is concerned with improving the design step of manufacturing both in terms of accuracy and efficiency.

Already for several decades now, the design of manufacturing processes has profited from numerical simulation methods. These methods were, and are still, used in order to facilitate the iterative design process. Instead of having to test each preliminary design directly in the manufacturing process, it is much more cost- and time-efficient to run these tests in a simulation environment. Furthermore, in more recent years, inverse design methods have gained traction in the field. These methods design the manufacturing process based on the desired product outcome with little to no intervention by the design engineer.

In particular the inverse methods profit immensely from CAD-compatiblity, allowing to tightly interlace these methods with the CAD/CAM process. Exemplified via the manufacturing processes of injection moulding [1] and metal cutting [2], we will demonstrate how CAD-based methods not only improve the integration into the overall design process, but also possess superior properties in terms of accuracy and efficiency.

Tailoring a mesh generator for 3D NEFEM to avoid de–featuring

Xi Zou*, Ruben Sevilla, Oubay Hassan and Kenneth Morgan

Key Words: exact geometry, NURBS–enhanced FEM, de–featuring, mesh generation

Contemporary industrial design requires building computer aided engineering (CAE) models suitable for simulation. This task is known to be a major bottleneck due to the excessive human intervention required when processing the upstream computer aided design (CAD) model. In general, generating meshes from a complex CAD model largely depends on the type of simulation, because of the numerous multiscale features which may or may not be negligible for the physical problem of interest. Traditional mesh generators produce small, often distorted, elements, when the mesh size desired by the problem exceeds the dimension of the geometric features. Large research efforts have been made into methods of de–featuring complex CAD models. However, fully automatised de–featuring has not yet been achieved. Firstly, it is not always possible to know in advance the effect of the de–featuring before actually performing simulations. Secondly, the de–featuring requirements differ from problem to problem, due to their physical nature. Finally, de–featuring also relies on the desired approximation level.

The NURBS–enhanced finite element method (NEFEM) circumvents this problem, through a complete separation of the geometric representation from solution approximation. The two concepts have been tightly coupled in the large majority of available solvers through the isoparametric concept. Within NEFEM, the geometric description uses the boundary representation (B–rep) information directly from the CAD model in the parameter spaces, whereas polynomial functions are used to approximate the solution in the physical space. This new paradigm avoids the need for de–featuring. In addition, the method allows discretisation of the CAD model with a mesh size that respects the user specification and is not restricted by the presence of small geometric features.

This work will present a new mesh generation technique, in which element faces may span across multiple surfaces and retain the exact B–rep. The mesh generation process will be detailed, including the new quality metrics that have been devised specifically for the NEFEM elements. Several examples will be presented to demonstrate the potential of the proposed technique.

Key Words: Inexact Newton methods, Non-smooth minimzation, A posteriori error estimation

The convergence of the standard Newton algorithm hinges on the smoothness of the target nonlinear system. There is a wide class of modified Newton algorithms that address the case where the standard method fails due to low regularity. In particular, we consider so-called smoothing Newton methods [4] where non-differentiable functions are replaced by smooth approximate counterparts. The amount of smoothing is proportional to a parameter that should decrease as the smoothed iterations progress.

We seek a criteria for the smoothing parameter using a posteriori error estimation. We consider PDEs arising from the minimization of a non-smooth energy functional. Thus, we may use a so-called primal-dual gap estimator. The estimator measures the error in a computed solution by invoking a dual maximization problem. In particular, the estimator provides a constant-free upper bound for the difference of the energy of the true and computed solutions.

This strategy has been applied recently to non-smooth minimization problems in [1], where the primal and dual problems are solved in a globally coupled manner and no smoothing is used. In this talk, we instead present a patchwise-local and decoupled solution of the dual problem [2, 3] and use a smoothing Newton method for solving the primal problem. We also compute estimators that target the smoothing, linearization, and discretization components of the overall error in the smoothed problems. This leads to an adaptive algorithm steering the mutual sizes of the components as in [3].

An Efficient Mixed FE-Formulation for Gradient Elasticity at Finite Strains

Johannes Riesselmann[1*] **and Daniel Balzani**[1]

[1] Chair of Continuum Mechanics, Ruhr University Bochum, Universitätsstraße 150, 44810 Bochum,
johannes.riesselmann@rub.de

Key Words: Mixed Finite Elements, Gradient Elasticity, Finite Element Discretization, Finite Strains

Gradient elasticity formulations enable the modeling of size effects, which appear when the scale of material heterogenities approaches the scale of the macroscopic mechanical fields. Furthermore, due to the higher regularity of the solution, corresponding numerical simulations remain mesh-independent, since they are free of geometry-induced nonphysical singularities, which appear in local models at e.g. sharp corners or crack tips of the modeled specimen. Since gradient elasticity models incorporate second-order deformation gradients, purely displacement-based finite elements require C^1-continuity, for which unstructured meshing and retaining compatibility with standard software are known challenges. Another approach is to introduce displacement gradients as separate discretization variable. Corresponding mixed FE-formulations require only to be C^0-continuous and thus, standard interpolation with piecewise polynomial functions is sufficient. However, due to the introduction of additional variables, the development of corresponding numerical schemes which are cost efficient, stable and robust, is essential. Here, a formulation is presented, in which similar to an approach proposed in [1] the internal elastic potential is formulated exclusively in terms of the displacement gradient variable. A constraint term incorporating a divergence-free Lagrange multiplier enforces the rotation part of the gradient variable to vanish, which is a necessary condition for gradient fields. In a second constraint term the divergence-free condition is enforced. The corresponding discretization follows the approach of [2], which enables static condensation of the first Lagrange multiplier and thus, keeping the number of degrees of freedom at a minimum, while maintaining suitable mathematical solution spaces. Moreover, as shown in [2], the discrete Lagrange multipliers corresponding to the second constraint are identified as an approximation of the displacement solution. Thereby, displacement boundary conditions can be incorporated directly avoiding the necessity of a pre- and postprocessing step (cf. [1]). In a displacement-driven numerical test on a domain with hole and non-connected boundary convergence is shown. Other numerical tests further show robustness for varying nonlocal constitutive parameters and increased computational efficiency compared to other mixed approaches (c.f. [1, 3]).

Key Words: *Mixed Finite Elements, Nonlinear Elasticity, Stability, Hourglassing.*

This contribution addresses the issue of artificial instabilities in discrete solutions obtained by various non-linear finite element formulations (cf. [2]) occurring under homogeneous stress states in elasticity problems. While avoiding locking is crucial for accurately capturing physical instabilities, it is often observed that some locking-free formulations suffer from artificial, non-physical instabilities, usually referred to as hourglassing (cf. [1], [3]).

Analytical stability analyses of simple reference problems are presented and compared to the discrete solutions. This allows assessing precisely the performance of various finite element formulations for a broad range of input data, e.g. element aspect ratio and elastic constants. The sources of the hourglass phenomena triggered by compressive and tensile stress states are highlighted and, on this basis, a simple strategy to construct stable and locking-free finite element formulations is proposed.

Key Words: finite element methods, global nonlinear analysis, sparse polynomial optimization, Gamma convergence, sum-of-squares relaxations

Computation of minima of nonlinear integral functionals (e.g. strain energy) is typically done by using a variation of Newton's method or a gradient descent method on the Euler-Lagrange PDEs associated to the functional. However, these procedures only guarantee finding an approximation to a local minimum, but say nothing of whether the solution is a global minimum of the functional, which often is the goal. Finding an algorithm that provably converges to a global minimum is a classical and fundamental challenge in many fields, including nonlinear elasticity, fluid mechanics, pattern formation and PDE analysis. In this work, we leverage theoretical tools from the fields of sparse polynomial optimization (within algebraic geometry) and finite element (FE) methods to present such an algorithm. The techniques include exploiting properties of sparse sum-of-squares (SOS) relaxations and Gamma convergence to prove convergence to a global minimum of a functional with a polynomial integrand as the mesh is refined and the moment-SOS relaxation order is raised. We present numerical examples which result in excellent approximations to the global minima of different nonlinear functionals, including the pattern-forming Swift-Hohenberg free energy in two spatial dimensions, even when one uses sparse SOS relaxations that are computationally cheaper, but lack convergence guarantees. Finally, we also outline how to extend these methods to PDE-constrained optimization problems and show some preliminary results in this context.

Dynamics and Locking of Shell Eigenmodes

Harri Hakula

Aalto University, Department of Mathematics and Systems Analysis, P.O. Box 11100, FI-00076 Aalto, Finland, harri.hakula@aalto.fi

Key Words: Shells, Locking, Asymptotic Analysis, *p*-Version

Shell structures have a rich set of features resulting from the interaction of the shell geometry and the deterministic parameter, the thickness of the shell, which is often modelled as a dimensionless quantity. In this talk the connection between the boundary layers (including the internal ones) and the smallest eigenmodes is discussed.

For shells of revolution the asymptotics of the smallest eigenmodes have been analysed by various authors and with the exception of some corner cases the overall behaviour is well understood [1],[2]. What is new here is that the the asymptotic convergence rates for the eigenmodes are shown to be tied directly to those of the corresponding internal boundary layers. Spatial resolution of the boundary layers in FEM is known to give rise numerical locking or loss of optimal convergence rate – in this case eigenlocking. Even in the case of eigenlocking, the individual modes converge at the predicted rate, but they appear out-of-order due to error amplification manifested in constants.

The numerical experiments cover all major shell geometries and a practical range of dimensionless thicknesses.

Hourglassing-Free Petrov Galerkin Enhanced Assumed Strain Finite Elements Insensitive to Mesh-Distortion for Nonlinear Solid Mechanics

Robin Pfefferkorn[1*] **and Peter Betsch**[1]

[1] Karlsruhe Institute of Technology (KIT) - Institute of Mechanics, Otto-Amann-Platz 9, 76131 Karlsruhe, Germany, {robin.pfefferkorn@kit.edu, peter.betsch@kit.edu}

Key Words: enhanced assumed strain, Petrov-Galerkin, mesh-distortion sensitivity, hourglassing-free

The enhanced assumed strain (EAS) method proposed by Simo et al. [5] is one the most successful mixed finite element methods. Despite its success and numerous improvements there are still some open issues. Two of which concern mesh-distortion sensitivity and hourglassing-instabilities.

MacNeal [2] has shown that the optimal element performance cannot be achieved with a symmetric stiffness matrix. This lead to a Petrov-Galerkin approach termed unsymmetric finite element method which effectively allows construction of mesh-distortion insensitive high order finite elements [4]. However, unsymmetric low-order elements are often complex, require many internal degrees of freedom or a priori knowledge of the material model [6, 1]. Recently, Pfefferkorn and Betsch [3] proposed a Petrov-Galerkin approach based on the EAS method which overcomes these drawbacks and allows a simple construction of high performance low-order elements.

The present contribution concerns the extension of this method to nonlinear hyperelastic and elastoplastic problems. Focus is put on an hourglassing free formulation which could be achieved by enhancing the spatial displacement gradient instead of the usual enhancement of the deformation gradient.

Key Words: Shear and membrane locking, T6-3i finite element, geometrically exact shell theory.

Since the pioneering works of Argyris in the parametrization of finite rotations, several alternatives to formulate a genuine geometrically exact shell theory have been devised. In general, the only way to tackle the problems resulting from such theories is the finite element method. However, conventional displacement-based finite elements tend to deliver a poor performance as the slenderness of such structures increase. Assumed Natural Strain (ANS) and Enchanced Assumed Strain (EAS) techniques are often used to alleviate the unbalance of the shape functions in reproducing certain limiting conditions.

In the present work the authors study the behaviour of the T6-3i triangular finite element [1, 2]. This surprisingly *simple* element is advantageous from the implementation point of view, as its elemental computations are extremely fast to perform. However, the fact that its rotation field is non-conforming raises concerns on its ability to always converge to the exact solution. Moreover, although its displacement field was designed to satisfy the Kirchhoff limit constraint (at least for linear analysis *shear-locking* is absent), its membrane behaviour does not satisfy the limit constraints when the element is curved.

The aim of the authors is to assess the behaviour of the element under varying thickness values. Linear *versus* nonlinear analysis are performed for both *flat* and *curved* geometries. It is shown that the type of analysis (linear *versus* nonlinear) has a strong influence on the quality of the results. Unlike linear analysis, in non-linear regime there is always a coupling between bending and membrane behaviour (even in the case of flat elements).

[1] Institute for Structural Mechanics
University of Stuttgart
Pfaffenwaldring 7, 70550 Stuttgart, Germany
e-mail: {willmann;bieber;bischoff}@ibb.uni-stuttgart.de

Key Words: *3d-shell model, Poisson stiffening, locking*

In recent years, there have been many developments in the field of 3d-shell models. Compared to standard shell models, 3d-shell models allow for thickness change [1]. When simulating with only one layer of elements across the thickness, it has proven important to include linear transverse normal strain into 3d-shell models to avoid a stiffening phenomenon, often referred to as Poisson thickness locking. This is done either using the EAS-method [2] or by a quadratic displacement field in thickness direction [3].

When simulating bending over small radii using certain 3d-shell finite elements in LS-DYNA, Fleischer [4] observed an additional stiffening effect, which remained unexplained so far. In case of large strain, the elements behave remarkably stiffer than a converged numerical reference solution, although measures to avoid Poisson thickness locking are included.

This contribution focuses on the explanation of the stiffening effect described above. The stiffening effect turns out to be of higher order, which means that it is present only in case of large deformations in geometrically nonlinear simulations. Furthermore, a method to avoid the stiffening effect is derived and its feasibility is confirmed by numerical results.

Quantitative Evaluation of Shear Stiffness on Nonlinear, Linear and Two Intermediate Degrees of Partly Nonlinear Strain in 3D Membrane Theory and 2D Disc Theory for the 9-Node-4-Corner Finite Element

Carsten Corte

Baustatik – Baudynamik – Numerische Modellierung
Thrasoltstraße 12, D-10585 Berlin, Tel. / Fax +49 – (0)30 – 347 87 – 178 / – 180

Abstract

3D nonlinear membrane theory is assumed by 2nd Piola-Kirchhoff stress tensor and Green-Langrange strain tensor or by Cauchy stress tensor and Euler-Almansi strain tensor. The governing partial differential equation for 3D dynamic in-plane tensile force equilibrium considers second-order spatial derivatives of 3D displacement. The 9-node-4-corner finite element with biquadratic interpolation functions on nodal undisplaced 3D coordinate in stress-free state and on nodal 3D displacement is applied for spatial discretization within 3D nonlinear membrane theory (static equilibrium; dynamic equilibrium) – that for 2D plane geometry and in-plane 2D displacement includes and represents 2D nonlinear disc theory – . Geometric element height-width ratios that deviate strongly from unit value one induce nonlinearly increasing element shear stiffness by linearly increasing element height-width ratio. The 2D plane case of the 9-node-4-corder finite element with unit element height two units of length and parameter varying width from 0.1 to 10 units of length is exposed to parameter varying static in-plane 2D boundary shear displacement from small strain inducing 0.01 units of length to large strain inducing 10 units of length. Since element shear stiffnesses for assumptions of nonlinear strain and linear strain differ from each other and for assumption of nonlinear strain shear stiffness highly nonlinearly increases with increasing element height-width ratio furthermore two different intermediate degrees of partly nonlinear strain are considered for evaluation. Comparison between element shear stiffnesses by assumptions nonlinear, linear and two intermediate partly nonlinear strains is drawn for the above parameter ranges. Appropriate approximation of nonlinear strain by linear strain and two intermediate partly nonlinear strains, respectively, is concluded for high element height-width ratios to keep element shear stiffness realistic, representative and practical within 3D curved geometries for 3D membrane (static and dynamic) computations by application of the 9-node-4-corner finite element. Comparison focuses on element shear stiffness itself, applied increment factor within equilibrium iterations until convergence and number of equilibrium iterations until convergence.

Unconditionally stable dynamic analysis of multi-patch Kirchhoff-Love shells in large deformations

Domenico Magisano[1*], Leonardo Leonetti[1] and Giovanni Garcea[1]

[1] Università della Calabria, 87036, Rende (Cosenza), Italy, domenico.magisano@unical.it

Key Words: Nonlinear dynamics; Large deformation; Stability; Kirchhoff-Love; Multi-body; Shells

One-step implicit time integration methods such as Newmark's schemes are only conditionally stable when used in large deformation analyses [1]. Simo and Tarnow proposed a simple method that guarantees unconditional stability by conserving the algorithmic energy in elastodynamics [2]. However, energy conservation is lost for other structural models as the Kirchhoff-Love theory, more efficient in the terms of spatial DOFs for thin shell problems, where the strain-displacement relationship is no longer quadratic. This work presents a numerical framework for long term dynamic simulations of structures made of multiple thin shells undergoing large deformations. The C1-continuity requirement of the Kirchhoff-Love theory is met in the interior of patches by cubic NURBS approximation functions, according to the isogeometric concept, with membrane locking avoided by patch-wise reduced integration [3]. A simple penalty approach for coupling adjacent patches, applicable to either smooth or non-smooth interfaces and either matching or non-matching discretizations is adopted to impose translational and rotational continuity [4]. The time-stepping scheme of Simo and Tarnow is generalized to achieve energy conservation for generally nonlinear strain measures and penalty coupling terms, like the nonlinear rotational one for thin shells. The method is based on a particular integral mean of the internal forces over the step, that includes Simo and Tarnow's method as a reduced quadrature rule, and has unconditional stability.

Key Words: Mesh adaptation, Mesh generation, High-order mesh, Interpolation error, Quasi-unit mesh

A significant part of recent research in mesh generation has been devoted to the generation of body-fitted curvilinear meshes. Curved elements on the boundaries mitigate the error caused by the approximation of curved geometries by straight-sided meshes. The natural extension of the use of curvilinear meshes is high-order mesh adaptation. Here, we propose a methodology aimed at the generation and adaptation of two dimensional curvilinear anisotropic meshes. The quadratic triangular elements follow the features of a numerical solution computed e.g. with the finite element method, allowing a reduced number of degrees of freedom for a comparable interpolation error. The metric tensor field used to generate the elements is defined based on an interpolation error estimate, using recovered derivatives of order up to three of the numerical solution. A quasi-unit straight-sided mesh is first generated by spawning points in the computational domain in such a way that two neighbouring points lie within the range of $[1/\sqrt{2}, \sqrt{2}]$ when computing distances with respect to the metric field, then by connecting them using a standard anisotropic mesh generator. Straight-sided edges are then curved by moving the mid-edge nodes to approximate the geodesic between the edges's extremities while ensuring the validity of the elements at all time. Topological operations such as curvilinear edge swaps and curvilinear small polygon reconnection (CSPR) are finally applied to the curved triangulation to further increase mesh quality, yielding a quasi-unit curved mesh with only valid elements. For a comparable complexity, adapted meshes exhibit a reduced interpolation error compared to straight-sided anisotropic meshes. Numerical applications, such as tracer advection and Von Kármán streets, are presented to illustrate the method.

Key Words: Mesh Optimization, High-Order Methods, Finite Elements, Adaptivity

We present a framework for adaptive optimization of high-order curved meshes. The optimization process is driven by information that is provided by the simulation in which the optimized mesh is being used [1]. We make the important choice to require only discrete description of the simulation feature to which to adapt to, e.g., the feature can be described as a finite element function on the mesh. This is a critical step for the practical applicability of the algorithms we propose and distinguishes us from approaches that require analytical information.

The discrete problem is formulated as a variational minimization of a chosen mesh-quality metric, utilizing a finite element extension to the Target-Matrix Optimization Paradigm [2]. The method primarily relies on node movement (r-adaptivity), but also has the capability to perform h-adaptivity steps when this can produce to the desired local mesh size [3]. We will also discuss our latest capabilities for surface fitting and tangential relaxation, which are enforced weakly by adding penalty terms in the objective [4]. These penalty terms connect the concept of mesh motion to the discrete finite element function that defines the desired node position.

Key Words: Structural models, reduced model, geometrically exact rod and shell, contact.

One of the main challenges that structural models face, both from theoretical as well as from the numerical standpoints, is their incorporation into continuum models. This is so because, while some problems are purely structural, many relevant problems in engineering and mechanics cannot be adequately represented only with reduced dimension models but greatly benefit from incorporating them as part of the physical model. For example, while a cable might be represented with enough accuracy using a string or a bar model, its anchorage onto a bridge pillar might require a full three-dimensional model if a faithful representation of the stresses is required. Connecting these two descriptions is far from trivial.

Among this kind of problems, maybe the most important class involves interactions between reduced order models and continua. In particular, fluid/structure interactions between such bodies are notably difficult and have only been partially resolved before. The interaction between a fluid and surfaces such as the ones of flags, parachutes, sails are complex to model, but even more with cables and beams.

Based on our recent work [1], we will present a methodology for the formulation of solids with the kinematics of geometrically exact rods and shells. By a variationally consistent procedure, the motion of points in these bodies is dragged by a structural theory, while the interactions (surface and body forces) are resolved at the continuum level, with full accuracy. The outcomes of this approach are slender bodies (rod-like, shell-like), with very few degrees of freedom that can be used with standard contact and interaction solvers, and combined with full 3D solids without add hoc interfaces.

Exploiting the ideas of the model projection and kinematic lifting, one obtains, if desired, exact rod and shell models that use three-dimensional material constitutive laws. With this, and without any constitutive projection, elastic *and* inelastic constitutive laws can be used in the context of reduced order theories.

Key Words: *fluid-structure interaction, beam theory, mixed dimensional PDEs*

For the computational analysis of slender structures, one-dimensional (1D) models are commonly used to reduce the computational cost of simulations. However, the coupling of three-dimensional (3D) continua with immersed 1D structures is not yet well investigated from the mathematical and computational standpoint, although it arises in applications of paramount importance such as biology, biomedical engineering, geoscience and the mechanics of reinforced materials. We leverage on a new framework to formulate and approximate coupled partial differential equations (PDEs) on manifolds with heterogeneous dimensionality [1,2,3]. On the basis of this theoretical knowledge, we study the mathematical formulation and develop numerical methods for fluid-structure interaction (FSI) that combine a 1D representation of the slender structure with a 3D formulation of the flow. It is known that 3D-1D coupled problems can be interpreted as 3D problems with concentrated sources (Dirac deltas) located on lower dimensional manifolds of the domain [4]. The solutions of such problems are affected by low regularity, which in turn reduces the ability to construct convergent and efficient approximation methods. The new approach that we propose overcomes the previous issue because it has the fundamental advantage to enable the approximation of the problem using Galerkin projections on Hilbert spaces [1,2,3]. For this reason, we are able to perform a rigorous convergence analysis of approximation methods, such as the Finite Element Method (FEM), applied to these problems [1,2]. First, we address some general aspects of 3D-1D mixed dimensional PDEs, with particular attention to their coupling, achieved by means of Lagrange multipliers combined with a suitable projection operator form the 3D solution space to the 1D space [3,5]. Second, we apply this approach to the case of the interaction between a beam and an incompressible fluid, described as a 3D-1D FSI problem. In this case, we compare different coupling strategies, putting into evidence the advantages of the proposed approach.

How Well Do Constraint Mixture Models Represent Fibrous Soft Tissues? A Comparison Against Embedded, Discrete Fiber Models

Sotirios Kakaletsis[1*], Emma Lejeune[2], Manuel Rausch[3]

[1] The University of Texas at Austin, Austin, TX 78712, USA, kakalets@utexas.edu
[2] Boston University, Boston, MA 02215, elejeune@bu.edu
[3] The University of Texas at Austin, Austin, TX 78712, USA, manuel.rausch@utexas.edu

Key Words: *Fibrous Soft Tissues, Embedded Fiber Networks, Timoshenko-Beam, Beam-to-Solid Coupling*

Fibrous soft tissue such as collagenous connective tissue or blood clot may be thought of as fiber network embedded in a homogeneous solid matrix, i.e., “ground substance” [1]. Models of these tissues are important to our understanding of their fundamental structure-function (or -dysfunction) relationship. In the past, various modelling approaches have been taken that spanned all the way from simplified continuum approaches up to a complete spatial modelling of the area-to-volume fiber-matrix interface [2]. Which begs the question: what is the exact trade-off between accurate description of the macroscale behaviour and model complexity? To answer this question, we developed models of the elastic, coupled bulk-fiber behaviour of fibrous soft tissues representing two distinct levels of model complexity. We compared their performance under three naturally occurring deformation modes, namely uniaxial extension, simple shear, and pure shear.

First, we develop a low-fidelity model, with a continuum approach of the fibrous tissue as an incompressible, anisotropic, hyperelastic material. This approach accounts for the fibrous structure in the strain energy function through a continuous probability density function of the fiber orientation. At the deformed configuration, the contribution of the fibers is spatially integrated over a unit sphere domain, as in the work by H. Chieh and G. Ateshian [3]. Next, as our high-fidelity model, we consider an embedded discrete fiber network into a hyperelastic solid matrix. We model each fiber as a spatial Timoshenko beam. Next, we couple the translational degrees of freedom of the beam’s centerline to the displacements of the solid matrix through a Lagrange multiplier field, as proposed in the mortar-type finite element method by Steinbrecher et al. [2]. Specifically, we implement the segment-based integration of coupling elements of initially curved beam networks and conduct proper consistency and convergence tests by developing a user subroutine on the commercial code Abaqus/Standard.

Using both approaches we will consider a representative volume element with one dispersed principle fiber bundle (single fiber family). We will investigate and report the ability of our high-fidelity model (embedded fiber network) to accurately capture the (de-) coupled behaviour of the fiber network and the solid matrix. Furthermore, we will particularly focus on the trade-off between model complexity and computational cost with respect to practical, experimental aspects of soft tissues mechanical testing under large deformation.

Key Words: *mixed-dimension method, embedded networks, 1d-3d coupling, root water uptake, tissue perfusion, smoothing kernel*

Mixed-dimension 1D-3D methods allow to efficiently describe systems tubular networks embedded in porous media where fluid is exchanged between network and the porous bulk and dominates the fluid distribution in the porous medium. Two examples of such systems are fluid flow in microvasculature and embedding tissue [1], and water uptake of plant roots from soil [2]. Due to the nature of thin inclusion fluid pressure profiles in the porous bulk usually exhibit large gradients in the vicinity of the inclusion and pose difficulties for numerical schemes approximating pressure profiles and fluid flow. For example, particularly for dry soils local water pressure gradients can be become very large in the vicinity of roots due to the nonlinear relationships of water saturation, water pressure and soil permeability. Commonly used discretization lengths (for example 1cm) in root-soil interaction models do not allow to capture these gradients accurately.
We present a numerical scheme targeted at resolving such issues. The numerical scheme combines smooth distribution functions in the vicinity of the network with interface reconstruction schemes based on local analytical solutions. We explore accuracy and limitations of the scheme in numerical test cases. We present the results of a recently published benchmark case and present the latest results regarding time-dependent problems of water uptake from soil or exchange of small molecules between microcirculation and embedding tissue.

Key Words: *Multiphysics Problems, Mixed-dimensional models, Solvers, Preconditioning, Fractional Laplacian operator*

We are interested in reliable simulations of biophysical processes in the brain, such as blood flow and metabolic waste clearance. Modeling those processes results in interface-driven multiphysics problems that can be coupled across dimensions. The coupling is imposed by the Lagrange multiplier that enforces constraints on the interface and ensures well-posedness in fractional Sobolev spaces weighted by material parameters. However, the complexity of the interface coupling often deteriorates the performance of standard methods to finding the numerical solution.

Therefore, we derive preconditioners and solution techniques which target specifically such multiphysics problems by exploiting fractional operators at the interfaces for order optimal performance. Specifically, the robust preconditioners for the interface problems are represented as a sum of fractional Laplacians that can include both negative and positive fractionalities. To handle fractional operators numerically, we implement methods based on multilevel algorithms and rational approximation. We show that the numerical methods are parameter-independent and scalable with regards to number of the degrees of freedom of the system. We demonstrate the efficiency of our methods on several numerical examples of mixed-dimensional problems on realistic geometries, such as 3D-1D model of flow in vascularized brain tissue.

Key Words: Robust solvers, operator preconditioning, Biot-Stokes coupling, Darcy-Stokes coupling, Perturbed saddle-point problems

Coupled multiphysics mixed-dimensional systems pose a special challenge for construction of solution algorithms which should remain efficient accross a wide range of model parameters typically found in the applications. It is known that if the coupling variable/Lagrange multiplier is explicit in the problem formulation such algorithms often require fractional order operators on the interface. In this work we consider formulations of the coupled Biot/Darcy-Stokes problems (solved for Biot displacement-total pressure-fluid pressure/Darcy pressure and Stokes velocity-pressure) which are free of Lagrange multipliers. We first show that sub-physics preconditioners are stable only in certain parameter regimes. Then, using an abstract theoretical framework we construct mesh-independent and parameter-robust monolithic preconditioners for both problems. A critical component enabling robustness are the appropriately weighted operators in fractional Sobolev and metric spaces at the interface. Several numerical examples using finite element and finite volume methods will be presented demonstrating performance of the proposed preconditioners.

Key Words: *Ferroelectric material models, anisotropic, polarization*

The FE-AFE Ceramic material model in the ALEGRA finite element code has traditionally been used to model inelastic strain and polarization changes of ferroelectric materials undergoing ferroelectric (FE) to antiferroelectric (AFE) phase transformations. However, this model has been shown to be insufficiently general under anisotropic (non-hydrostatic) stress loading.

An extension to this model based on a different transformation strain mechanism at the crystal scale was proposed based on an analysis of crystallographic data. This model extension was implemented as a proof of concept in Python [1], and the resulting simulations show significant improvement in agreement with experimental data.

In this talk, we will describe the FE-AFE Ceramic material model and show the limitations of the old approach, in which the transformation criterion and inelastic transformation strain for a domain depends on the orientation of the dipole vector. We will then describe the new approach, in which both dipole and crystal orientations are considered, and show that better agreement with experimental results is achieved with this new approach.

SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.

Keywords: *Energetic materials; Piezoelectricity; Flexoelectricity; Dielectric breakdown.*

Materials such as poly(vinylidene fluoride-co-trifluoroethylene), or P(VDF-TrFE), are known to exhibit piezoelectric and flexoelectric behaviors. While numerous studies have been performed to predict the conditions under which chemical reactions initiate (ignition threshold) as a result of thermal and mechanical dissipation mechanisms, there is a need to develop additional physical means for effecting the ignition process for precision control and multifunctionality. Electromechanical excitation, which takes advantage of the underlying piezoelectric and flexoelectric behaviors of materials, is a prominent candidate mechanism. We report for the first-time a computational simulation framework that demonstrates that hotspot formation resulting from an internal dielectric breakdown is a previously under-explored mechanism for ignition.

The material considered here is an electroactive composite film comprising a copolymer matrix of P(VDF-TrFE) and embedded aluminum nanoparticles (~9% in volume fraction) subject to impact loading. To simulate the impact from a free-fall weight with variable drop-heights, a boundary velocity corresponding to the drop-height is prescribed. In addition, an electric field (*E*-field) is generated throughout the matrix, owing to its electromechanical properties. Both poled and unpoled P(VDF-TrFE)/nAl films are examined to assess the effect of poling. While piezoelectricity exists only in the poled films, flexoelectricity is present in both poled and unpoled films. To quantify the statistical variations in the behavior out of inherent material heterogeneities, a SEMSS (statistically equivalent microstructure sample set) with five random samples is generated and used.

Two successive analyses are performed. First, a fully-coupled mechanical-electrostatic analysis is carried out to establish the *E*-field induced by the piezoelectricity and flexoelectricity, leading up to the initiation of dielectric breakdown. Next, a coupled electrodynamic-thermal analysis is performed using the *E*-field obtained from the electrostatic simulation. Local temperature rise caused by resistive heating during the breakdown process and the local melting of the matrix are both accounted for, enabling us to accurately model the development of hotspots (i.e., critical regions characterized by localized high temperature) near the nAl particles. The hotspot field is used to establish the conditions for the onset of self-sustained chemical reactions in the film. The results show that piezoelectricity and flexoelectricity are essential mechanisms for charge accumulation that can ultimately lead to dielectric breakdown, hotspot development, and the initiation of exothermic reactions, with flexoelectricity having more significant contributions. Specifically, the poled films have ignition times ~10% shorter than those of the unpoled films. The findings are in good agreement with the accompanying experimental measurements.

Simulating Nonlinear Domain Reorientation and Phase Transformation Phenomena in a Micromechanical Ferroelectric Model

Wen Dong[1]

[1] Computational Materials and Data Science Department, Sandia National Laboratories, Albuquerque, NM 87185, USA, wdong@sandia.gov

Key Words: *Ferroelectrics, Phase Transformation, Domain Reorientation, Power Supply.*

Ferroelectric generators (FEG) are often employed in pulsed power applications to deliver a short high-voltage and high-current pulse within a compact low maintenance design. FEGs deliver power by subjecting a ferroelectric element to a powerful mechanical shockwave that releases electrical bound charge by triggering nonlinear phenomena such as domain reorientation and phase transformation and less significantly piezoelectric response. Simulation challenges for FEGs arise from the difficulty in creating accurate nonlinear ferroelectric material models. Domain reorientation and phase transformations are difficult to model due to their anisotropic, nonlinear, and hysteretic behavior arising from irreversible changes in electric domain microstructure.

This work presents a micromechanical model that has been developed to accurately capture both domain reorientation and phase transformation phenomena in ferroelectrics. The micromechanical approach allows the approximation of the domain microstructure and nonlinear and an energy-based transition criteria is employed to govern changes in domain reorientation and phase transformation changes in the micromechanical framework. The ferroelectric micromechanical model is demonstrated for lead-zirconate-titanate (PZT) 95/5, a common ferroelectric material used in FEGs. PZT95/5 can be induced from ferroelectric to antiferroelectric phase through the application of compression due to a reduced unit volume in the antiferroelectric phase and in FEG applications display both domain reorientation and phase transformation behavior.

Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525. [3]*Institut Universitaire de France (IUF)*

Key Words: mesh deformation, finite element, phase-change

The eXtreme MESH deformation approach is a new method to follow sharp interfaces without remeshing and without changing the mesh topology [1]. Moreover, the interface may change topology (nucleation, coalescence, splitting). The key idea is to allow elements to reach zero measure. This permits interface relaying, annihilation and seeding in a time continuous manner. The presentation will target the Stefan phase-change model in which the solidification front carries a temperature gradient discontinuity.

Traditional tracking approaches like the Arbitrary Lagrangian Eulerian (ALE) method are able to follow interfaces but cannot handle properly change of topologies of these interfaces. Other capturing approaches based on fixed meshes and enrichment strategies (as the extended/generalized finite element methods) may handle topological changes but at the cost of carrying extra degrees of freedom implying a special book-keeping and technical issues (as ensuring the time stability of the scheme with an evolving number of degrees of freedom).

The X-MESH keeps a fixed number of unknowns and a classical finite element approximation. The mesh deforms while keeping its topology. The nodes located on the solidification/melting front are not always the same because the front is relayed by the nodes. Examples demonstrating the capability of the X-MESH to handle nucleation and front coalescence will be shown during the presentation.

Key Words: *Violin, Time evolution, Vibration, Acoustics, Numerical simulation*

The vibration and the sound field around the body of an old violin made by Stradivari are studied in this paper, where the highly precice geometry of the violin is scanned using a micro-CT scanner. After the noise in the scanned data is eliminated using a CAD software for post-processing, the geometry data are saved in the simulation software[1].
Assuming the orthotropic properties of woods (spruce and maple), the major vibration modes of the violin[2], such as A0, center bout rotation, B1-, B1+, and the acoustic pressure level at the surface of the violin body are calculated using the finite element method.
Next, using the sound pressure distribution at the surface of the instrument, the sound pressure spreading in a rectangular box simulating a concert hall is calculated with the open-source parallel acoustic analysis software: ADVENTURE Sound [3][4]. It is concluded that the sound pressure in the hall radiated from the violin is successfully simulated.

Key Words: partitioned analysis, symmetric formulation, coupled thermoelastic problems, thermo-mechanical analysis, finite element method

This paper presents a partitioned symmetric formulation of transient coupled thermoelastic problems. The thermoelastic problem is multiphysics problem in which the wave (i.e. hyperbolic type) equation and the diffusion (i.e. parabolic type) equation are coupled. The classical formulation of thermoelastic problems is non-symmetric and has the paradox of infinite propagation speeds of thermal signals. As a result, the direct approach of this whole system is uneconomical, and special kinds of algorithms are required to solve the classical form. Based on this motivation, we introduce a partitioned symmetric formulation of thermoelastic problems. To do this, we construct two separate variational formulations of the uncoupled thermal conduction and uncoupled structural systems. These two uncoupled variational expressions are augmented by the constraint of energy exchanges between the elastic body and the thermal conduction body via the method of Lagrange multipliers. Finally, this paper suggests a solution algorithm including implicit-implicit time integration strategies, and the present partitioned formula is verified by one- and two-dimensional examples.

This work proposes a new Fluid-Structure Interaction computational framework for the solution of dynamic coupled problems. The coupling between the solid and an ALE incompressible fluid is formulated by means of the method of localized Lagrange multipliers (LLM) [1]. Instead of applying a direct coupling between the fluid and structure meshes, which is the traditional approach, LLM introduces an intermediate surface with its own degrees of freedom that is connected to the fluid and structure sides using independent fields of localized Lagrange multipliers. This approach facilitates the connection of non-matching meshes and allows us to derive explicit dynamic equations for the interface. The principal advantage of these dynamic interface equations is the uncoupling of the structure and ALE fluid problems, that now can be solved in parallel. Numerical experiments with the proposed methodology are used to prove its efficiency and accuracy by running a series of classical dynamic FSI benchmark problems.

Key Words: preCICE, partitioned coupling, porous medium, black-box methods

Many real-world applications involve porous-media multi-physics problems. Common applications are hydraulic simulations, where the hydromechanical coupling of a liquid in a fracture under high pressure and the resulting deformation of the surrounding porous medium is simulated, or the coupling of free and porous-medium flow, as it appears in simulations of water over a riverbed. In these cases, the problem can be split into two non-overlapping subdomains that are separated by a sharp interface. In each of these subdomains, the physical behavior and thus also the mathematical models to represent this behavior differ greatly. As a result, solving such a coupled problem using monolithic approaches leads to systems of equations that are ill-conditioned.

We present partitioned schemes that solve the problems on the subdomains individually in an iterative procedure. This allows us to reuse existing solvers for the resulting linear systems of equations while avoiding the assembly of the ill-conditioned monolithic system. The coupling of the subdomains is achieved by appropriate exchange of information over the sharp interface separating the subdomains and incorporating this information in coupling conditions. The iterative procedure is stabilized and accelerated by suitable interface quasi-Newton methods. Our focus is on black-box coupling methods that approximate the interface problem via information exchanged over the coupling interface. This black-box approach simplifies the reuse of existing software packages that are tailored to solve the individual subproblems. The couplings are carried out via the open-source coupling library preCICE [1] that has many useful features such as data mapping, data communication, parallelization, etc. already implemented. We study the behavior of different coupling schemes for hydromechanical coupled problems [3] and coupled free and porous-medium flow problems [2] to identify suitable coupling configurations.

Key Words: *3D woven composites, Multi-scale analytical model, Strength prediction, Damage mechanics, Mechanical characterization*

Three-dimensional (3D) woven composites are being increasingly used in aerospace and automotive industries because of their better interlaminar fracture toughness, higher damage tolerance and improved mechanical stability [1]. To expedite their analysis and design efficiency, it is necessary to develop simple and accurate modeling tools capable of quickly evaluating their mechanical properties and progressive failure.

In this paper, a generic multi-scale analytical model for predicting stress-strain response and progressive failure behavior of 3D woven composites is presented. Firstly, based on apt geometrical approximation and assumptions, the unit cell (UC) of composite is firstly identified and reconstructed into a refined lamina structure with multiple equivalent lamina elements (ELEs). Micro-mechanical model (Chamis model [2]) is applied to estimate the elastic and strength properties of each ELE. Secondly, two-way coupled stress-strain responses between the UC (macro-scale) and ELE (meso-scale) are established through a bottom-up homogenization procedure and top-down localization procedure. Finally, a progressive damage model, which consists of damage initiation criteria (Hahisn-Hou failure criterion) and a stiffness evolution strategy (equivalent displacement method [3]), is employed to predict damage initiation and progression of the ELE.

The validated model is then used to evaluate the predictive capability of different unit cell model schemes and to investigate the effects of geometric parameters on stiffness and strength properties of 3D woven composites. The results indicate that the interior-surface integrated cell model scheme has the overall best performance in predicting mechanical properties of composites. In addition, an exponential model and a linear model are proposed to quantify the relationships between the number of weft layer and yarn density and mechanical properties, respectively. The present results demonstrate the analytical model can be a useful tool to provide an insight for the analysis and design of a range of 3D woven composites.

Key Words: *Modified zigzag theory*, *Sandwich beams*, *Free vibration*, *Natural frequency*, *Graphene reinforced composite*

With the extraordinary mechanical properties, graphene is regarded as one of the most attractive reinforcements for composite materials. However, for the natural frequencies prediction of functionally graded graphene reinforced composite (FG-GRC) sandwich beams, the current high-order models confront obstacles because of the ignorance of compatible conditions for interlaminar stresses. In this work, a modified zigzag beam theory is proposed for free vibration analysis of FG-GRC sandwich structures, which take into consideration the compatible conditions of transverse shear stresses at the interfaces of adjacent layers. Meanwhile, to enhance the accuracy of dynamic analysis, the Reissner's mixed variational theorem and preprocessing method of three-dimensional (3D) elasticity equations are adopted and implemented in the present method. The analytical solutions for such sandwich beams with simply supported conditions were provided by utilizing Hamilton's principle, and evaluated through comparing with 3D elasticity solutions as well as the results from existing high-order beam models. The numerical results demonstrate the precision of the proposed model in predicting natural frequencies of the sandwich beams. Subsequently, detailed investigation are carried out to explore the influences of the graphene volume fractions, distribution patterns, stacking sequences and other geometric parameters on the natural frequencies of FG-GRC sandwich beams.

Local Refinement of Structural Kinematics for Failure Onset Analysis via Neural Networks

Marco Petrolo*, Alfonso Pagani, Pierluigi Iannotti and Erasmo Carrera

MUL2 Lab, Department of Mechanical and Aerospace Engineering, Corso Duca degli Abruzzi 24, 10129, Torino, Italy, marco.petrolo@polito.it, www.mul2.com

Key Words: *CUF, Node Dependent Kinematics, Failure, Neural Networks, Composites*

The proper prediction of failure onset concerning load levels and spatial distributions is fundamental in the performance analysis of composites. A common approach is based on evaluating failure indexes obtained from combinations of stress components at any given point, and the resolution of the stress field affects the failure onset prediction. In composite structures, the complete 3D stress field – in-plane and transverse components – is necessary for many practical applications due to the anisotropic nature of the material. A typical example is the stress field around free edges where transverse shear and axial stress are dominating. However, proper numerical models to detect such fields tend to be cumbersome due to the necessity of using highly refined 3D meshes. An alternative approach is based on refined structural models to build 1D or 2D finite elements and relax aspect ratio constraints [1,2].
The use of Neural Networks (NN) in structural problems is increasing [3] due to their flexibility and ability in dealing with nonlinearities. This paper proposes a novel use of NN in combination with Node Dependent Kinematics structural models in which each node of the finite element discretization can assume a different structural theory. NDK is useful to augment the resolution of the model locally. NN is trained using different distributions of nodes to predict failure indexes. The output is the optimal refinement of the model concerning the structural model's order and where to use it. The use of the trained NN is helpful to localize the most critical areas to be modelled and set the proper structural model to use.

Key Words: *Unidirectional FRP, Random Fiber Location Variation, Image-based Machine Learning, Microscopic Stress Field*

Composite materials are composed of multiple materials and are used in various fields because they have better material properties than single materials. However, random dispersion of the apparent material properties is larger than the case of the homogeneous materials, and a large dispersion of several properties such as apparent strength sometimes causes severe problems.

One of the reasons of this dispersion may be caused by random dispersion of a microscopic stress field in composites, but for example, even in case of a unidirectional fiber reinforced composite, it is difficult to predict the effect of random fiber location variation on microscopic stress state of the composite. A relationship between the arrangement of inclusions and stress state has been discussed in a few literature [1], but a general relationship in multi-inclusion problem seems to be unknown.

From this background, it is important to reveal influence of inclusions arrangement, in particular with considering randomness and uncertainty in the microscopic scale, on microscopic stress field and the apparent material strength. It is desirable to estimate the maximum stress and the location of its occurrence based on each fiber location, and the analyses with an image-analysis-based deep learning [2] or numerical information-based deep learning [3] were attempted. These reports suggested applicability of the machine learning for the analysis, but it was not clear whether a microscopic stress field was well learned or not.

From this fact, in this paper, applicability of the image-analysis-based machine learning to microscopic stress field estimation at each location in microstructure is investigated. Values of stresses at each location is learned, and accuracy and validity of the learning procedure are discussed with comparison of the previous learning results on maximum stresses and their occurrence location.

Key Words: Composite laminates, Homogenization method, Computational continua

In practice, composite structures may exhibit more than two length scales. The O(1) homogenization method has been often employed in analyzing composite materials but had limited use for laminated structures. Since the composite plates or beams are often modeled as plane or one-dimensional structural elements (beam elements, shell elements and so on), periodicity in the existing multiscale analysis methods is mostly considered in the axial direction for beams and the in-plane directions for plates. This difficulty should be overcome based on an appropriate composite laminated theories.

O(1) homogenization method and computational continua (C^2) approach are employed to the multiscale analysis of composite beams and plates. Firstly, a two scale layerwise multiscale analysis method (LMAM) is established based on the RLWT and O(1) homogenization method for the composite laminated plates, considering the periodicity in in-plane and along the thickness direction simultanenously. And then, the two-scale and three-scale C^2 models of composite curved beams are developed; the four-node isoparametric beam elements based on the TSDT is employed to discretize the coarse-scale problems of composite curved beams, and the nonlocal quadrature scheme is employed to replace the classical Gauss quadrature since the size of Computational Unit Cell (CUC) is comparable to the size of the coarse-scale element. And then, a three-dimensional M^2 method is developed to analyze the local displacements and stresses in the woven composite laminate. The refined meshes in the every scale unit cells are regarded as the super elements, and their contributions on the macroscopic stiffness are smeared into the total stiffness matrix of macroscopic problem. The displacement continuity and internal force equilibrium at the interface between two different scale CUCs are ensured by a continuity equation set. At last, two-scale and three-scale C^2 models are extended into the composite laminated plates and woven plates based on the macroscopic TSDT and solid elements.

Due to the intrinsic nature of aerospace engineering, structural weight has always been an aspect of utmost importance during the design stages of aircraft and spacecraft. Indeed, light alloys were preferred for the construction of such structures until the irruption of composite materials. Currently, composite materials might represent more than 50% of the structural components of aircraft thanks to its mechanical properties and improvements in manufacturing techniques. In the recent years, fabrication procedures have been oriented to the additive manufacturing strategies, such as automated fibre placement or fused deposition modelling, which lead to multi-layered structures. As mentioned before, weight optimisation is one of the key steps in structural design. However, nowadays procedures, such as polar [1] or lamination [2] parameters, are based on assumptions that may shrink the design space. In this work, a direct optimisation genetic algorithm (GA) [3] is proposed. The presented GA is able to deal with discrete- and continuous-valued design variables, as well as including a multispecies capability, and new genetic operators. In this manner, several laminated structures can be considered at the same time in the optimisation loop in order to find the least-weight design that fulfils certain structural requirements. The latter are calculated by means of an in-house finite element code based on the well-known Carrera Unified Formulation (CUF) [4], in which high-order structural models can be obtained and used to analyse the mechanical performance of multi-layered structures.

Advances in composite structures have permitted the conception of novel manufacturing techniques, such as Automated Fibre Placement (AFP) or Fused Deposition Modelling (FDM), that allow engineers to develop new families of laminated components. Indeed, thanks to these advances, variable angle tow (VAT) [1] laminates have increased their presence in aeronautic applications. Macro and mesoscale analyses of VAT structures has become available during the last decades, mainly focused on the buckling and post-buckling [2] behaviour. In the recent years, high-order finite elements, based on the Carrera Unified Formulation (CUF) [3] have been employed to analyse the free vibration [4] and stress prediction [5] of VAT plates and shells. Likewise, mesoscale failure onset [6] and buckling performance [7] affected by meso and microscale uncertainty defects has been addressed. However, due to the complexity inherent to the multiscale behaviour of composites, inner scales might have been disregarded when studying VAT composite components. In this manner, this work aims to analyse the microscale stresses that arise in the mentioned laminates subjected to uncertainty defects. For doing so, Mechanics of Structure Genome (MSG) is coupled with CUF [8] to provide: (i) homogenised material properties used in the macro/mesoscale analysis; (ii) retrieve the microscale stress state by providing the mesoscale strain state. Then, the latter can be utilised to calculate failure onset at the innermost scale of the structure.

Transverse Crack Characterization of Fiber-Reinforced Composites: High-fidelity and Data-Driven based Methods

Maryam Shakiba[1*], and Reza Sepasdar[2]

[1] Virginia Tech, 750 Drillfield Dr., Blacksburg, VA, USA, mshakiba@vt.edu, shakiba.cee.vt.edu
[2] Virginia Tech, 750 Drillfield Dr., Blacksburg, VA, USA, sepasdar@vt.edu

Key Words: Transverse Cracks, Machine Learning, Fiber-Reinforced Composites, Damage

Transverse cracks often are the first damage mechanisms starting in unidirectional plies of cross-ply fiber-reinforced composite laminates under multiaxial loading. Transverse cracks propagate towards the bounding plies and cause inter-ply delamination, which in turn reduces the structural integrity and undermines the mechanical performance. This work first integrates an efficient finite-element-based numerical framework with robust and accurate constitutive equations to study transverse behavior and multiple cracking of cross-ply fiber-reinforced composite laminates. The considered constitutive equations include elastic, elastoplastic damage, and cohesive zone models to simulate fibers, matrix, and fiber/matrix interfaces, respectively. The effect of fiber/matrix cohesive interface properties on the transverse crack density and delamination is investigated.

The developed high-fidelity framework is then used to generate a database to train a machine learning algorithm and predict the nonlinear stress distribution and failure pattern in microstructural representations of such composite materials. An image-based deep learning framework is developed. The deep learning framework contains two stacked fully-convolutional networks. A physics-informed loss function is also designed and incorporated to improve the performance of the proposed framework further and facilitate the validation process. It is shown that the proposed deep learning approach can predict the composites' post-failure full-field stress distribution and failure pattern, two of the most complex phenomena to simulate in computational solid mechanics, with an accuracy of 90%.

Data-driven Control of Bioaerosol Concentration by Inlet Air at a Recirculation Area Involved Indoor Corner

Zhang Xingyu[1*], and Li Hua[2]

[1] Department of Engineering Mechanics, Beijing University of Technology, Beijing 100124, People's Republic of China, xingyu0711@bjut.edu.cn

Key Words: *Two-phase flow modelling, Machine learning, Recirculation area, Indoor air quality*

Indoor air quality attracts rich attention to the resident health, especially after the epidemic wreaks havoc all over the world. The air pollutants, such as virus, pollen, spores and fragments of fungi usually suspend and move with the indoor air as the form of bioaerosol. The recirculation area is found in an indoor corner, restricting the air-exchange with fresh air and providing a stable and comfortable for bioaerosol accumulation and growth. This research presents a novel concept to reduce the local bioaerosol concentration at indoor corner, via the actuated inlet air from ventilation outlet, through a data-driven controller design method. The feasibility of the proposed method is firstly analysed by a theoretical gas-particle flow model, in which the trajectory of a chaotic vortex is controlled to modulate the recirculation area by a data-driven orthogonal design scheme. The simulation results prove that inlet flowrate designed by a proper control signal reduce the local bioaerosol concentration successfully. Subsequently, the gas-particle laminar corner flow model is simulated by a commercial computational fluid software. The recirculation area at the corner is determined mathematically by the minimum net mass flux principle via grid search. A neural-network-based model predictive control is trained and designed to generate the control signal of inlet flow rate. The proposed control approach reduces 27.52% more bioaerosols than that without control interfere.

Deformation-diffusion coupled material model for paper including visco-elasticity and visco-plasticity

Manfred H. Ulz[1*], Tristan Seidlhofer[2] and Ulrich Hirn[2]

[1] Institute of Strength of Materials, Graz University of Technology, 8010 Graz, Austria, manfred.ulz@tugraz.at

[2] Institute of Bioproducts and Paper Technology, Graz University of Technology, 8010 Graz, Austria - CD Laboratory for Fiber Swelling and Paper Performance, tseidlhofer@tugraz.at, ulrich.hirn@tugraz.at

Key Words: Paper Mechanics, Paper Curl, Visco-plasticity, Diffusion, Finite Deformation

Paper is a material that is known for being sensitive to moisture changes, which renders its mechanical behaviour hard to predict. We propose a hygro-mechanical model for paper sheets that captures the transient behaviour during the paper's interaction with water. The proposed model provides insight into the interaction of mechanical dissipation phenomena in paper during liquid induced swelling. Such phenomena are relevant in industrial applications, e.g. for understanding paper deformation due to printing and packaging, as fluting and curl of paper depends on the generation of (dissipative) plastic strains [2].

The present work introduces a new model to the literature by employing a deformation-diffusion coupling in the logarithmic strain [3] and fluid concentration space [1]. We motivate a fully coupled theory since the diffusion of water within the paper network happens on a similar time scale as the mechanical relaxation phenomena. The switch to the logarithmic strain space is chosen as the incorporation of anisotropy can be performed in a straightforward manner and various mechanical effects (e.g. visco-elasticity and visco-plasticity) can be combined more easily. Besides, the absorbed water induces a large increase in volume which requires the application of finite strain theory. The model is derived in a thermodynamically consistent manner and its parameters are fitted to experiments available in the literature. The model yields a good agreement of numerical results with paper curl experiments and provides further insights into this complex multi-physics problem.

Effect of High Mechanical Loading on Intervertebral Disc Calcification

Qiaoqiao Zhu[1*], Xin Gao[2]

[1] Nanjing University of Aeronautics and Astronautics, 211106, zqq@nuaa.edu.cn
[2] Nanjing University of Aeronautics and Astronautics, 211106, xingao@outlook.com

Key Words: *High Mechanical Load, Intervertebral Disc Calcification, Multiphysics, Charged Ions Transport*

High mechanical load (above physiological range) is related to spinal diseases such as intervertebral disc (IVD) degeneration and scoliosis, in which disc calcification has been observed. However, it is unclear whether high mechanical load is directly related to disc calcification. Thus, this study was aimed to investigate the effects of large mechanical load on the potential of IVD calcification inducement through anaylzing the intradiscal change of calcium (Ca^{2+}) and phosphate (Pi) concentrations under mechanical overload using a modeling approach.

A multiphysic mixture theory based finite element model of IVD was adopted [1] and extended to study the transport of Ca^{2+} and Pi in the negatively charged disc under three different levels of diurnal load, each consisting of an 8-hour rest at 100 N of compressive load and a 16-hour creep under compression at 500 N, 650 N, and 800 N, respectively. The disc was assumed to be in the electroneutrality state, the total charge of all ions (Na^+, Cl^-, c^F, Ca^{2+}, Pi) is zero,where c^F is the fixed charge density of the disc. In the disc, Pi exists in two forms, either dihydrogen phosphate ($H_2PO_4^-$), or mono-hydrogen phosphate (HPO_4^{2-}), the ratio of these two forms was determined by the Henderson-Hasselbalch equation. At pH of 7.2 in the disc, the valence of Pi is -1.5. The ultrafiltrable levels of Ca^{2+} (1.1 mM) and Pi (1.1 mM) in the serum were assigned as boundary conditions.

Concentrations of Ca^{2+} (denoted as [Ca^{2+}]) and Pi (denoted as [Pi]) in the IVD varied under diurnal mechanical load. In the nucleus pulposus, [Ca^{2+}] varied in the range of ~7-10 mM, [Pi] varied in the range of ~0.20-0.26 mM under normal diurnal load (100 N/500 N). Under large load, [Ca^{2+}] increased, but [Pi] decreased. The production of [Ca^{2+}] and [Pi] (denoted as Ca×Pi) was largest in the cartilaginous endplate (CEP) among all subregions of the IVD under all three loading conditions. The value was less than 2.4 mM^2 under normal diurnal load, but it was higher than 2.4 mM^2 under high load(i.e., 100 N/800 N).

Our simulated concentrations of Ca^{2+} and Pi were consistent with experimental data [2]. Mechanical load has significant effects on the spatial-temporal distribution of [Ca2+], [Pi], and Ca×Pi. Under high loads, our calculated value of Ca×Pi in the CEP reached the range (2.4-4.0 mM^2) for spontaneous precipitation of hydroxyapatite[3]. Our results indicate that high mechanical load may increase the potential of IVD calcification.

ABSTRACT: Architected structural material is a class of materials integrating material properties and geometry, exhibiting new and highly customized behaviour that significantly filled up the empty spaces in Ashby plot as well as introduced new properties not available before. Based on published investigations and finding, the unique combination of structural design, enhancement and material constituent of these architected materials allow them to achieve extraordinary mechanical properties such as lower mass per unit volume, higher specific energy absorption per unit volume, high impact absorption, and more, compared with standard bulk materials. However, previously published work focused on investigating the effect of a single structural enhancement, such as hierarchy, graded, corrugated, etc**,** combined with cellular topologies, on the mechanical properties of the design. This work aims to develop a novel design principle, through both experimental and simulation investigation of the effect of combining of three or more structural enhancement into designs, and double optimisation with both conventional multi-objective algorithm and machine learning.

Key Words: *DUCTILE FRACTURE, COHESIVE CRACK, TRESCA YIELD FUNCTION, DAMAGE MECHANICS*

The contribution of this study is to propose a cohesive traction embedded constitutive law [1] combined with Tresca yield function and shear-induced damage variable for a mixture with flat and shear-lip fractures in ductile failure. The two types of the fractures are represented by cohesive traction--separation law and shear-induced damage, since it is well known that these mechanisms are different from each other. For the flat fracture, the material stiffness reduction and strain softening due to void nucleation, growth, and coalescence under high stress state are realized by the cohesive traction separation law that determines the process of stress releases along with ductile crack opening. To realize crack nucleation at arbitrary location and propagation in an arbitrary direction, the cohesive separation law is combined with the Hencky-type hyperelastic-plastic model by the introduction of apparent strain due to crack opening and local balance equations between cohesive tractions and principal stresses. On the other hand, for the shear-lip fracture, the shrink of yield surface caused from the evolutions of voids in a shear band is presented by the shear-induced damage variable that is incorporated into the Tresca yield function. Moreover, the evolution of shear-induced damage is determined by the damage loading function corresponding to the plastic energy release based on thermodynamics [2]. Simple numerical examples are presented to demonstrate that the proposed constitutive law enables us to predict differences between flat and shear-lip fractures according to the thickness of specimens.

Key Words: *Crystal Plasticity, Porosity, Porous RVE analysis, Homogenization; HCP crystals*

An efficient and effective crystal plasticity model is proposed for porous HCP crystals subject to a variety of multiaxial loading conditions. These conditions include (i) uniaxial, biaxial, and triaxial, (ii) tension and compression, (iii) low and high triaxiality, and (iv) axisymmetric and non-axisymmetric loadings. The framework is based on a combination of variational homogenization, phenomenological extensions, and assumptions motivated by observations from the high-fidelity micromechanical analysis. A novel penalty-free algorithm is employed to reach and maintain a specified stress state while performing representative volume element (RVE)-based crystal plasticity finite element (CPFE) analysis with porosity. The RVE studies demonstrate that the initial porosity, crystallographic orientation, and stress states have a significant effect on the homogenized mechanical responses of microscopically porous RVEs. The proposed porous crystal plasticity model is developed and calibrated using a database generated from the results of micromechanical RVE analysis. The calibrated porous model is reasonably effective in predicting the response of porous crystalline RVEs.

Key Words: *Crystal plasticity, Homogenization, Lath microstructure, Ti-alloys*

Near α and $\alpha + \beta$ Titanium alloys are widely used in aero-engine applications due to their excellent specific properties and thermal stability at moderately high temperatures. The microstructure of these alloys consists of equiaxed α grains having hexagonal closed packed structure and transformed colonies with alternate laths of α and β (body centred cubic structure) phases. The specific properties of these alloys can be optimized for a given application by modifying the volume fraction and sizes of these microstructural features; though such alloy designing solely using experiments can be expensive. Lately, Crystal Plasticity Finite Element Method (CPFEM) based analyses are being widely used to compliment the materials design process. However, a major challenge of using CPFEM based analyses for these alloys are the disparate length scales of the laths, and the colonies and equiaxed grains, in the same Representative Volume Element (RVE). In order to address this challenge, homogenized models of lath microstructure based on Taylor and virtual single crystal assumptions have been developed in the literature. However, these models fail to capture the traction balance at the interface on the homogenized response and hence lead to inaccuracies [1].

In the present work, an improved homogenized model has been developed that allows the interface to relax by undergoing a periodic motion while satisfying traction balance. Size dependency has been introduced by assigning anisotropic Hall-Petch based strengthening of slip systems depending on the Burgers Orientation Relation (BOR) between the α and β phases [1]. The homogenized model has been implemented as a user material subroutine pluggable into ABAQUS. The accuracy of the model has been evaluated by comparing its responses with CPFEM simulations of a single alternating α and β lath unit subjected to periodic boundary conditions following asymptotic expansion based homogenization. The other two existing models have also been considered in the comparative study. Two shear and two extensional deformation histories for two different Euler angles have been considered in the study. The comparison of the volume-averaged stress-strain responses showed that the model developed in this work is consistently more accurate than the other models. The phase stresses and slip activity in the developed model were also observed to be much closer to the corresponding volume-averaged responses obtained from the CPFEM simulations of single lath unit. The study clearly shows that the homogenized model developed in this work can be applied to perform CPFEM analysis of RVEs of near α and $\alpha + \beta$ Titanium alloys to predict both the macroscopic and local responses accurately. The model can also be applied to other material systems having a lath microstructure.

Accelerated Multiscale Simulations of Heterogeneous Materials using Machine Learning with Knowledge Transfer

Leong Hien Poh*, Zhongbo Yuan

* National University of Singapore, leonghien@nus.edu.sg

Key Words: *Computational Homogenization, Machine Learning*

Engineering composite materials are largely heterogeneous in composition at the (macro) structural scale. In many complex applications, a predictive analysis of the structural performance is required. The grand challenge is to achieve a model with minimal constitutive assumptions and parameter calibrations at the macro-scale, while simultaneously retaining a similar level of predictive capability as direct numerical simulation (DNS) with full microstructural details, at a fraction of the computational cost required by the latter. One popular approach to achieve these competing objectives is to adopt a so-called FE-NN framework. At the micro scale, sampling points are generated by applying a macro deformation field to a representative volume element (RVE), over a wide deformation range, and extracting the corresponding homogenized response of the RVE. These sampling points thus form the database for the training of a homogenized surrogate model via Neural Network (NN), to be incorporated into a standard FE framework for analyses at the macro-scale.

The FE-NN framework has been shown to accelerate the structural analyses drastically, with predictions matching closely with DNS. One major limitation of the conventional FE-NN framework, however, is the huge database required for the training of surrogate model during the offline phase. In many applications, it was shown that the computational cost of setting up the surrogate model is comparing to a DNS, hence rendering it an impractical strategy for most applications. In this presentation, we focus on the computational cost during the offline phase of the FE-NN framework. Departing from the conventional approach, we first adopt a source model for the pre-training of surrogate model. The trained parameters are next downloaded for the training of the desired target model, to complete the offline training phase with knowledge transfer (KT). It is shown that the proposed KT-FE-NN framework reduces the computational cost greatly, compared to the conventional FE-NN approach. The predictive capability of the KT-FE-NN framework is demonstrated for several examples, benchmarked against DNS.

Advances in Practical Multiscaling

Jacob Fish, Andrew Beall and Yang Yu

Columbia University

Abstract

In my talk I will report on advances in developing a practical multiscale framework, including:

(i) A novel reduced order homogenization (ROH) approach based on nonuniform phase eigenstrain influence functions resulting in a response that is much closer to the first-order classical homogenization than existing ROH approach based on the uniform eigenstrain influence functions;

(ii) A pseudo-nonlocal fully integrated linear hexahedral macroscopic finite element based on reduced integration for stress updates but full integration for element matrices (residual and its consistent tangent stiffness);

(iii) A Bayesian Inference (BI) of the parameters of ROH where Neural-Network is first trained using the ROH, and then used as a surrogate model during the BI process; and

(iv) A coupled thermo-chemo-mechanical ROH for predicting residual stresses in fiber-reinforced polymer composites.

Atomistic-Continuum Multiscale Simulation of Polycarbonate Under Different Strain Rate Deformations

Key Words: *Finite Element Method, Molecular Dinamics, Polycarbonate, Multiscale Simulation*

Polycarbonate is attracting attention as an engineering plastic with excellent impact resistance. In many applications, polycarbonate is used in environments where the stresses and impacts above the yield point are applied, such as external walls. Therefore, it is expected to analyze the behavior of polycarbonate before and after yield stress at different strain rates.

The yeilding is caused by the microvoids in the material[1]. However, It is difficult to trace the microvoids in the material at each strain by experiment. Molecular dynamics simulations at a large scale as in actual phenomenon take high analysis costs. Finite element simulations cannot represent the phenomenon of yielding due to microvoids. Therefore, the atom-continuum multiscale simulation is necessary to solve these problems in polycarbonate.

Kubo et al. developed a model for the coarsening of polycarbonate[2]. Urata et al. applied atomic-continuum multiscale simulations to amorphous solids[3]. Xu et al. measured stress-strain curves for polycarbonate at high strain rates (on the order of 10^3 s^{-1}) [4]. However, atomic-continuum multiscale simulations have not been performed on polycarbonate, a polymeric amorphous solid. Also, the behavior of microvoids at higher strain rates (the order of 10^5 s^{-1}~) is unclear.

In this study, molecular dynamics simulations are used to investigate the effect of increasing microvoids on yield stress. By applying the results to finite element simulations, the yielding of polycarbonate on the continuum scale is clarified from the viewpoint of the molecular scale.

Coarse-Grained Atomistics at Finite Temperature by a Gaussian Phase Packet-Based Quasicontinuum

Dennis M. Kochmann[1*], Prateek Gupta[2], Shashank Saxena[1] and Miguel Spinola[1]

[1] Department of Mechanical & Process Engineering, ETH Zürich, Leonhardstr. 21, 8092 Zürich, Switzerland, dmk@ethz.ch (mm.ethz.ch)

Key Words: Multiscale Modeling, Quasicontinuum, Molecular Dynamics, Finite Temperature

Although being powerful simulation tools, atomistic techniques such as molecular dynamics (MD) come with severe restrictions: while only relatively small samples can be simulated, finite-temperature MD suffers from unrealistically high loading rates due to the time step limts of explicit time integration. Here, we discuss a finite-temperature quasicontinuum (QC) framework, which promises to overcome the aforementioned limitations by (i) spatially coarse-graining the atomistic ensemble based on a fully-nonlocal, energy-based QC approximation [1, 2] in an updated-Lagrangian setting, and (ii) using a statistical mechanics-based Gaussian Phase Packet (GPP) formulation for quasistatic finite-temperature calculations [3]. We show that the GPP ansatz includes the maximum-entropy QC formulation as a special case and captures local adiabatic heating due to atomic motion. Spatial coarse-graining limits full atomistic resolution to those regions of the simulation domain, where it is indeed warranted (e.g., in the vicinity of defects), while efficiently coarsening away from those regions. We discuss the fundamental concepts and the advantages and disadvantages of this simualtion framework, and we present a suite of example results, including dislocation interactions, grain boundary and surface properties of metallic materials as functions of temperature (comparing selected representative results to LAMMPS data for validation). Combined with automatic adaptivity, our simulation framework makes for a powerful toolbox for finite-temperature equilibrium and non-equilibrium simulations that overcome the length and time scale limitations of MD.

Computational Homogenisation of Shear-deformable Shell Models accounting for Mesoscopic Damage in Laminated Composites

Aewis K.W. Hii*, Bassam El Said and Stephen R. Hallett

Bristol Composites Institute, University of Bristol, BS8 1TR, United Kingdom.

Key Words: *Second-order homogenisation, cohesive elements, shear-deformable shell, laminate damage*

The progressive failure behaviour of large aerospace composite components is driven by damage phenomena that take place at the sub-millimetre length scale. The numerical analysis of these problems using full-scale high-fidelity modelling is often impractical, as the required computational resources increase exponentially with the structural size.

This work proposes a multi-scale framework that utilises shear-deformable shell and high-fidelity solid models at the structural and laminate length scales, respectively. The scale transition is handled using second-order computational homogenisation [1], where the mesoscopic damage events are described using the suite of progressive damage models developed at the Bristol Composites Institute (BCI) [2]. The downscaling constraints, consisting of a combination of surface and volume integrals, are derived based on a set of orthogonality conditions [3] with account for the cohesive interface elements at the fine scale. Due to the former consideration, both the curvature and transverse shear strains are accurately transferred from the shell to the solid models, showing no dependency on the RVE size for pristine (undamaged) laminates. During upscaling, the generalised shell constitutive laws are formulated in terms of the Taylor-bound and the fluctuation matrices [4], taking into account the stiffness contributions from the fine scale cohesive interface elements.

The proposed concurrent framework is implemented in the commercial finite element software Abaqus, where the nested FE^2 analysis is activated only for the shell material points in the critical regions. The framework performance is demonstrated through a series of comparative studies between full-scale and multi-scale models for flat and curved laminated composite panels.

Key Words: Computational Homogenization, Reduced-Order Model, Poroelastic Materials

Currently, available soundproofing materials are crucial for mitigating noise in the automotive, aeronautical and building industries. They have remarkable performance at the mid- and high-audible frequencies. To obtain materials also applicable in the low-audible frequency range, it has recently been proposed in [1] to embed small particles within the material structure. As demonstrated in [1], the foam-like structure with a mass-spring effect creates bandgaps that can be tuned to target frequencies in the same fashion as locally resonant acoustic metamaterials (LRAMs). Wave propagation modeling in poroelastic materials poses computational challenges because of fine-scale processes at the pore level, for instance, air-solid drag forces, interacting with large-scale acoustic waves in the so-called subwavelength regime. In general, combining this intrinsically multiscale problem with finite-size geometries at the application (macroscopic) level becomes rapidly infeasible to solve due to limited computational resources. Multiscale reduced-order modeling arises as a promising approach mostly because it can preserve a high-fidelity model when a representative basis is selected, opening the opportunity to efficiently perform design optimization.

In this work, a transient computational homogenization framework is proposed for describing the dynamic macroscopic response of poroelastic materials with locally resonant components at the microscopic level. Extending the approach proposed in [2], the model is capable of capturing emerging exotic features such as bandgaps as well as the macroscopic Biot-like behavior of regular acoustic foams. Component Mode Synthesis is applied to reduce the fluid-structure microscopic problem based on a static-dynamic decomposition. Consequently, the formulation explicitly accounts for the contributions of the internal dynamics to the macroscopic physical quantities. Numerical examples demonstrate the efficiency and suitability of the proposed multiscale approach.

Key Words: Computational Homogenization, Dual-Phase Steel, Martensite/Ferrite interface, Substructure Boundary Sliding, Damage, Enhanced Cohesive Law

Martensite/ferrite (M/F) interface damage largely controls dual-phase (DP) steel failure. Several M/F interface models have been proposed in the literature, which however do not incorporate the relevant microphysics. Indeed, it has been recently suggested that the martensite substructure boundary sliding dominates the M/F interface damage and should be accounted for, placing a need of multi-scale frameworks. Moreover, depending on the activation of sliding, two distinctive M/F interface damage modes may occur: along the interface in case of inactive sliding; towards the ferrite matrix in case of active sliding, and both can lead to interface separation at the mesoscale. The sliding-induced interface damage mode nevertheless cannot be described with the existing multi-scale interface modelling frameworks. Therefore, a homogenization framework targeted for the M/F interfaces is developed. At the mesoscale, a DP steel mesostructure consisting of multiple martensite islands embedded in a ferrite matrix is modelled, with the M/F interfaces placed in between. The kinematics over the mesoscopic M/F interfacial zone entails a displacement discontinuity (and a deformation discontinuity) across the interface, which is internally enhanced by the sliding-induced kinematics. At the microscale, a M/F interfacial zone unit cell resolving the martensite substructure is considered. The martensite laths and inter-lath retained asutenite (RA) films are described using the crystal plasticity model. The ferrite matrix is described using a continuum damage model which incorporates the volumetric and deviatoric damage modes. Consistent with the mesoscopic interface description, two effective internal displacement jumps associated to the non-sliding- and sliding-induced interface damage modes, respectively, are defined from the correlated microfluctuations. Furthermore, applying the Hill-Mandel condition leads to the generalized interface tractions conjugated to these internal displacement jumps. Finally, an enhanced interface cohesive law is formulated, which accounts for two distinctive M/F interface damage modes. Numerical examples demonstrate the unit cell size-objectivity of the enhanced interface cohesive law obtained using the proposed homogenization methodology, and its power on modelling the M/F interfaces efficiently.

[3] University of Naples Federico II, Via Claudio, 21 - 80125 - Naples, Italy, elio.sacco@unina.it

Key Words: NTFA, multi-scale analysis, homogenization, reduced order modeling

We propose an extension of Non-Uniform Transformation Field Analysis (NTFA) [1] to address modeling of heterogeneous materials undergoing debonding. We denote the proposed method as Enhanced Non-uniform Transformation Field Analysis (ENTFA). Departing from the NTFA-based homogenization proposed in [2], we enhance it by introducing a consistent tangent matrix, and we formulate the enhanced approach for both single and multi-scale analyses. In the multi-scale setting, we adopt a suitable representative volume element of the micro-scale and model debonding with cohesive interfaces obeying the interface law in [3]. As in [2], the interfaces are partitioned into sub-interfaces, and the inelastic relative displacement field within each sub-interface is approximated by piecewise linear functions. This allows the inelastic relative displacements to be represented using reduced inelastic variables, which are solved for through a Newton-Raphson iterative approach based on the obtained consistent tangent matrix. This not only facilitates the derivation of the homogenized stress-strain constitutive relation at the macro-scale, but also allows to robustly trace complex snap-back phenomena in single-scale analyses by the application of an arc-length control technique. Several numerical tests demonstrate that ENTFA leads to a significant reduction of the computational time over reference non-linear finite element analyses, while retaining a satisfactory accuracy.

Key Words: nonlinear plate, homogenization, prestrain, microstructure

The presence of prestrain has a tremendous effect on the mechanical behavior of slender structures leading to complex equilibrium shapes showing spontaneous bending, symmetry breaking, and wrinkling. We aim at predicting equilibrium shapes of microheterogeneous, prestrained, composite plates in the case of bending driven shape shifting. To this end we introduce a new approach that blends analytic and numerical methods. We start with a 3d nonlinear elasticity model for a periodic material that occupies a plate-like domain with small thickness. We consider a spatially periodic prestrain modelled via a multiplicative decomposition of the deformation gradient. By simultaneous dimension reduction and homogenization in the spirit of [1], we rigorously derive (in the Γ-limit of vanishing thickness and period) an effective, nonlinear bending model for plates with an emergent spontaneous curvature term in the plate model. The effective properties of the plate model (bending stiffness and spontaneous curvature) are characterized corrector problems. The general theory of Γ-convergence implies that minimizers of the effective plate model approximate minimizers of the original 3d problem, and thus, we study the dependence of equilibrium configurations of the derived plate model on properties of the 3d-composite. We do this exemplary for a parametrized sandwich plate with periodically distributed, prestrained fibres. To assemble the 2d-model, we first evaluate the homogenized properties of the 2d model by solving the corrector problems numerically (via standard Lagrange FEM). We then investigate the equilibrium shapes predicted by the 2d model. In the spatially homogeneous case, the problem reduces to an algebraic, non-convex minimization problem that can be easily solved numerically. In the general case, we appeal to a minimizing movement scheme to numerically approximate critical points of our plate model (this is a delicate task due to the presence of non-convex isometry constraint).

Our study reveals a rather complex dependence of the equilibrium shape on the considered parameters. E.g., the curvature and principal directions of the shape feature discontinuities in dependence of the volume fraction of the fibres; symmetry break: shapes may bend in directions that are neither parallel nor orthogonal to the fibre direction; size effects: strong dependence on the aspect ratio between the plate thickness and composite's period.

Key Words:*UD-CFRTP, Numerical Material Tests, Nonlinear mechanical behaviour*

Unidirectional carbon fiber reinforced thermo-plastics (called "UD-CFRTP") not only possess anisotropic material responses, but also exhibit peculiar nonlinear material behavior depending on temperature and time [1]. The previous studies have suggested that such behavior could be characterized by performing numerical material tests (called "NMTs") with six macroscopic deformation modes (three vertical directions x, y, z and three shear directions xy, yz, zx) using the finite element (FE) model of a unit cell based on the homogenization method [2]. However, this setting is questionable especially when we examine the inelastic material behavior of UD-CFRTP under off-axis loading.

This study examines the anisotropic, nonlinear material behavior of UD-CFRTP under off-axis loading by conducting NMTs with more than six modes and proposes a method of identifying appropriate material properties of an assumed macroscopic anisotropic constitutive law. Specifically, seven macroscopic deformation modes (three vertical directions, three shear directions, and a deformation pattern in the off-axis direction of 45 degrees) are considered to prepare the virtual material responses to identify the macroscopic material properties by using an optimization method. To verify the identification accuracy, we compared the predicted macroscopic material responses with those obtained by the actual off-axis tensile test. In consequence, the extensive use of the NMTs technology with seven macroscopic deformation modes has enabled us to confirm that the material properties of the assumed macroscopic constitutive law for UD-CFRTP can properly be identified using the NMTs results with the off-axis macroscopic deformation mode in addition to the standard six ones in comparison with those using only six modes. It thus concluded that seven macroscopic deformation modes are indispensable for properly determine the nonlinear material behaviour for off-axis UD-CFRTP.

Key Words: Interphase, General interface, Interface elasticity, Cohesive interface, Interface position

Finite-thickness *interphases* between different constituents in heterogeneous materials are often replaced by a zero-thickness *interface* model. Well-established interface models intuitively assume that the interface layer is situated exactly in the middle of its associated interphase [1]. Furthermore, it is commonly accepted that this assumption is necessary to guarantee the balance of angular momentum on the interface. While the interface may coincide with the mid-layer of a uniform interphase, we argue that this assumption fails to sufficiently capture the behavior of graded or inhomogeneous interphases. We rigorously prove that the interface position does not necessarily have to coincide with the mid-layer in order to satisfy the angular momentum balance. This presentation introduces a novel interface model called extended general interface model which allows for arbitrary interface positions [2, 3]. The presented extended general interface model is essentially based upon the *weighted average operator* instead of the commonly *classical average operator*. Next, via incorporating this *extended general interface* model into homogenization, we develop bounds and estimates for the overall moduli of fiber-reinforced and particle-reinforced composites as functions of the interface position and properties. The significance of the interface position is demonstrated via a series of examples where the interface position is identified based on a full resolution interphase. Our presentation reveals several unfamiliar aspects of heterogeneous materials embedding interfaces and provides a deeper understanding of size-dependent behavior of materials [4, 5].

Key Words: Multiscale Computational Homogenisation, Composites, Multiphysics Problems

The electrification of aircraft requires significant improvements to be made in thermal management, weight reduction, energy storage and electrical distribution. The use of multifunctional composites is essential in these endeavours and provides an effective way to significantly reduce the mass of components by using existing structural elements to perform additional functions. In fibre-reinforced composites, the mechanical and physical properties are highly anisotropic – with superior tensile strength, stiffness, thermal and electrical conductivities occurring in the fibre-direction rather than transverse and through-thickness directions. By tailoring the combination of fibre, resin system and nano-reinforcement used; these properties can be fundamentally optimised and significantly improved. However, the electrical and thermal behaviours of composites are poorly understood, particularly for complex geometries with different stacking sequences. The use of hierarchical, multi-physics modelling is essential to further this understanding to optimise both the micro-structural and macroscopic design of fibre-reinforced composites in a time-frame unachievable through manufacture and experimentation alone.

To understand this behaviour more thoroughly, a multi-physics, finite-element (FE) model has been produced to characterise the electrical and thermal conductivity of fibre-reinforced composites at the micro-scale. The 3D fibre architecture and resulting contact between adjacent fibres are responsible for the anisotropic conductivity. This fibre architecture has been reproduced using Bezier curves [1] to approximate fibre distributions from X-ray computed tomography data of 8552/IM7 composites [2]. A controlled degree of fibre overlap has been allowed, to form connections between adjacent fibres. The fibre architecture and its complementary matrix form a representative volume element (RVE). By applying periodic boundary conditions, an entire ply of material can be represented by a conductivity tensor given from Monte Carlo simulations of the micro-structure. Through rotational transformations of this tensor, a full laminate can be modelled using its stacking sequence. The model is capable of considering a variety of material combinations and ply stacking sequences to predict their electrical and thermal behaviour in a geometrically complex component. The detailed prediction of a composite's electrical and thermal behaviour is essential in developing the next generation of multifunctional materials.

Key Words: *Ferroelectrics, Domain pattern formation, Polycrystal, Finite temperature, PZT*

The thermo-electro-mechanical coupling and the unique property to permanently alter their atomic-level electric dipole moment (polarization) makes ferroelectric ceramics a promising active material for various engineering applications, e.g., in sensors, actuators, storage devices, energy converters, medical and communication industry. The complex coupling mechanism of ferroelectric materials requires multiscale modeling, reaching from the atomic level across the polycrystalline mesoscale to the macroscopic device level.

Based on a novel finite-temperature phase-field framework [1,2], which accounts for the temperature dependence of the DFT-informed Landau potential as well as thermal fluctuations, we perform high-resolution simulations of the ferroelectric domain evolution in a micron-sized polycrystal with an atomic-unit-cell spatial resolution by exploiting the parallel efficiency of the FFT-based numerical implementation. Results indicate that the switching kinetics of the effective material can be traced back to the evolution of the underlying domain pattern formation. The collective motion of domain walls, their interaction with grain boundaries, and the nucleation of new domains at the microscale result in a dependence of the homogenized material response at the macroscale on the loading rate of the applied electric field. Increasing the electric field rate at constant magnitude leads to a decrease of the remnant polarization, which agrees with measurements. Moreover, we observe realistic laminate-like structures within grains and show the impact of electric field rates on the domain pattern formation, which provides a deeper understanding of the emerging ferroelectric microstructure as well as its connection to piezo- and dielectric properties.

We present the development, realization, and validation of our finite-temperature phase-field framework and discuss its application to bulk polycrystalline (tetragonal) lead zirconate titanate and barium titanate to study the kinetics of ferroelectric ceramics, which demonstrates better predictions than competing models.

Multi-scale Modelling of Emergent Dynamic Metamaterial Behaviour in Linear and Non-linear Regimes

Varvara Kouznetsova[1*] **and Marc Geers**[1]

[1] Eindhoven University of Technology, Eindhoven, The Netherlands,
v.g.kouznetsova@tue.nl, m.g.d.geers@tue.nl

Key Words: Multi-scale Modelling, Computational Homogenization, Metamaterials, Wave Dispersion

Dynamic metamaterials exhibit emergent coarse scale wave dispersion behavior due to interactions between propagating mechanical waves and fine scale micro-inertia mechanisms, based on either localized resonance or Bragg scattering, or their combination. This opens new possibilities for advanced wave manipulation applications, e.g. tunable waveguides, adaptive passive vibration control, superdamping, acoustic diodes, cloaking and focusing, noise insulation and (vibro-acoustic) energy harvesting. The development and design of such materials and devices made thereof, requires advanced modelling techniques, capable, on one hand, to deal with complex geometries, boundary conditions and excitations, and, on the other hand, computationally more efficient than direct numerical simulations.

This talk will present a multi-scale technique towards efficient analysis of initial boundary value problems involving dynamic metamaterials of local resonance type in linear and non-linear regimes. The proposed approach originates from the classical computational homogenization, well established for quasi-static problems, an extension of which to transient problems has recently been developed. For linear problems, the static-dynamic decomposition can be used to derive the closed form homogenized equations representing an enriched effective continuum, in which additional kinematic degrees of freedom emerge to account for micro-inertia effects [1]. The application of this approach to metamaterials with negative effective mass, negative refraction index and attenuation of flexural vibrations of metamaterial beams and plates [2] will be illustrated. In non-linear case, fully coupled two-scale transient computational homogenization is used to study the wave dispersion in finite size macroscopic structures [3], demonstrating various phenomena emerging due to the presence of non-linearities, e.g. amplitude dependent attenuation response, higher-order harmonics generation and energy exchange.

Efficient multiscale simulation of finite deformations of soft composites and metamaterials requires the homogenization of effective constitutive models from microstructural simulations. Such effective material models must comply with continuum mechanical requirements, i.e., the laws of thermodynamics, material frame indifference, material symmetry, growth conditions, and ellipticity. While analytical models may not be flexible enough to capture the highly nonlinear behavior of soft microstructures such as beam lattices, data-driven models are more flexible, but so far they do not consider all requirements [1]. In this work, we present a data-driven constitutive modeling framework for the multiscale simulation of microstructured materials, which conforms to the physical model requirements by construction [2]. The strain energy function is formulated as an input-convex feed-forward neural network to fulfill the polyconvexity condition, which implies ellipticity. Two approaches are introduced: A model based on a set of polyconvex, anisotropic and objective invariants, and a highly flexible model that is formulated in terms of the deformation gradient, its cofactor and determinant. When calibrated with the challenging homogenization data of cubic beam lattices with instabilities, the invariant-based model shows drawbacks for several deformation modes. The model based on the deformation gradient alone is able to reproduce and predict the effective material behavior very well. Only a moderate amount of physically motivated calibration data is used, which shows the excellent generalization capabilities of these physics-guided data-driven constitutive models. Subsequently, the application in sequential multiscale simulations [3] and the extension towards parametric [4], inelastic and multi-physical materials are discussed.

Key Words: *Powdered Materials, Homogenization, Multiscale, Compaction Process*

Powder materials are used in a wide range of applications including mechanical parts, pharmaceuticals and foodstuffs. The factors that affect the properties include not only the conditions related to the particles such as raw material, size distribution and surface treatment, but also the molding process such as granulation, filling, agitation, and milling. In particular, although compaction is an important process that determines the properties of the final product, there are few studies that have analysed numerically the material behavior in detail.

Material behavior of powders have been analytically predicted mainly by the discrete element method (DEM) [1]. However, DEM represents the rigidity of materials by adjusting the interaction forces between particles, so it is not possible to observe the deformation of individual particles. In this study, we conduct multiscale analysis of the compaction process by means of numerical material testing based on homogenization method [2] using finite element method (FEM) to predict mechanical behavior of powder materials. In order to create a microstructure model used for the analysis, we developed a Monte Carlo based algorithm which was confirmed that the filling rate close to the theoretical upper limit could be achieved in a very short time. We prepared two models having the particle size following uniform and Gaussian distribution. A numerical material tests were performed by defining the material properties for each particle as Elasto-plastic characteristic and macroscopic boundary conditions corresponding to the molding process. From macroscopic material responses obtained by averaging the results in microstructure, it was confirmed that the response depends strongly on the size distribution of the particles, and it can also be curve-fitted well by the Drucker Prager material constitutive law.

Key Words: *Viscoplasticity, Kinematic Hardening, Static Recovery, Numerical Material Testing*

The static recovery is one of the relaxation terms associated with Armstrong-Frederick type kinematic hardening model and contributes to representing the rate-dependent mechanical behaviors of thermoplastic resin under non-monotonically loading[1], e.g., stress relaxation, strain recovery, and cyclic viscoplasticity. The present study examines the effect of the static recovery on the macroscopic rate-dependent mechanical behaviors of fiber-reinforced thermoplastics, comprised of thermoplastic resin and fiber material, using a method of numerical material testing[2]. The pure elasticity is applied to the fiber material for the sake of simplicity. On the other hand, the constitutive model of thermoplastic resin is adopted that of Launay et al.[3] which is slightly modified by considering the static recovery. Numerical material testing is conducted on the unit cell for unidirectional-reinforced thermoplastics after the constitutive model of thermoplastic resin is implemented to user-defined subroutine UMAT in the commercial software of finite element analysis ABAQUS. We discuss the obtained omni-directional macroscopic rate-dependent mechanical behaviors of fiber-reinforced thermoplastics and provide the guideline toward the establishment of a macroscopic constitutive model to realize a decoupled multiscale analysis.

Key Words: Microstructure reconstruction, Random heterogeneous media, Homogenization

A very relevant but comparatively little-researched aspect of multiscale simulations and homogenization is the generation of the microstructure geometry based on image data. While special cases like fiber composites have well-defined micro-scale geometries, many engineering materials are random heterogeneous media. For these complex materials, the exact micro-geometry is stochastic and unknown. While digitizing the full 3D geometry of a specimen through computed tomography or serial sectioning is often technically impossible or prohibitively expensive, obtaining microscopy images of one or few cross-sections can be much more feasible. In this contribution, differentiable microstructure characterization and reconstruction (DMCR) [1, 2] is presented, an algorithm that (1) efficiently constructs plausible 3D volume elements based on one or few 2D slices, (2) generates either one RVE or a set of SVE, and (3) can smoothly interpolate between different microstructures.

Unlike comparably efficient reconstruction algorithms, DMCR uses generic high-dimensional microstructure descriptors such as spatial n-point correlations. The advantages and disadvantages in comparison to faster and less general approaches in the literature are discussed as well as the range of applicability.

The novelty of this contribution is a rigorous validation of DMCR using real 3D data. For this, a single slice is extracted from the 3D data to mimic the case that only a 2D microscopy image is available. The reconstruction from this slice is compared to the original 3D data regarding the microstructure morphology and the homogenized properties. Using these two metrics, various parameters like the required number of cross-sections and their resolution are discussed in depth. Overall, this validation demonstrates the range of applicability of DMCR, allowing the homogenization community to assess its potential. This creates a basis for a plethora of possible future works that harness both microstructure reconstruction and numerical homogenization to advance scale-bridging simulations of complex materials.

Key Words: *surrogate model, computational homogenization, history dependency, numerical material test, infinitesimal strain*

We propose a novel surrogate model for homogenized material behavior with history dependency. In recent years, data science techniques were introduced into the field of computational mechanics, and some kinds of surrogate models and data-driven methods have been developed to replace the classical constitutive model. In most recent, the history-dependent material behaviors represented by elastoplasticity have been paid exclusive attention as the target problem to be reproduced by the data scientific methods [1, 2]. Also, the applications of such methods for multi-scale problems have been studied in the interest of reduction of computational costs [3]. However, to the best of our knowledge, there has not been any surrogate model which can reproduce the homogenized stress-strain curves of composite materials with elastoplasticity including the unloading process. For that purpose, we developed a surrogate model which is capable to take the places of the macroscopic elastoplastic constitutive models within the infinitesimal strain theory. At first, to obtain the historical data of the macroscopic stress-strain relationships, we conduct numerical material tests on a representative volume element (RVE) by giving the various patterns of strain. Employing the macroscopic stress-strain history, we derive the histories of the macroscopic internal variables such as plastic strain and its accumulated quantity based on the computational homogenization theory. Arranging these historical data and performing some algebraic operations, we obtain a data set that represents the macroscopic constitutive relationship of the RVE. Using this data set, we construct a surrogate model by means of radial basis function interpolation with taking the step of the optimization of two hyperparameters. As the optimization method, we employ differential evolution, a well-known genetic algorithm. In the optimization process, we also perform cross-validation which saves the number of training data and ensures robustness in terms of variation of the input data for the surrogate model. In the presentation, we will conduct a surrogate computation of the load / unload problem of an elastoplastic material to verify the applicability of the proposed method for practical use.

Due to advances in modern manufacturing, there is an increased need for accurate and efficient simulation capability for microarchitected cellular structures. We define a cellular structure as a large macrostructure composed of individual cells, where the cells fit together to define the macrostructure. The cells need not be identical, the macrostucture may consist of a combination of solid material cells, plate-like cells, and truss-like cells. There exists a variety of asymptotic methods for simulation of cellular structures that are derived by assuming a separation of scales (infinitely small unit cells), with the detailed geometry of a unit cell replaced with a solid material with effective or apparent material properties [1]. The classic homogenization method, which assumes a periodic structure and uniform strain to compute the effective materials properties of the cell, is the most popular of these asymptotic methods. These asymptotic methods are quite efficient, but these approximations may not be accurate enough for critical applications. Conversely, the proposed Reduced Order Model (ROM) approach does not introduce effective or apparent material properties, but instead models the displacement of the unit cell by higher order polynomials. The proposed ROM is of intermediate complexity, it is more efficient (and less accurate) than a fully resolved finite element simulation, but more accurate (less efficient) than homogenization.

The proposed ROM begins with a highly resolved finite element mesh of a unit cell. A complete set of specially chosen high-order polynomial surface displacements is applied to the unit cell, and for each displacement the resulting force is stored. The resulting displacement-to-force map has units of stiffness, and after a change of variables this map can be used a drop-in replacement for a local high-order finite element stiffness matrix in a high-order finite element simulation of the macrostructure. The procedure is reminiscent of some FE2 methods [2][3], the key difference is that proposed ROM is based on high order polynomials. The overall approach is that a library of ROM's for different cells can be computed just once (offline phase), and used over and over again for difference macrostructures (online phase). In this presentation it is shown the proposed ROM converges to the full finite element solution as the order of the ROM is increased. In addition, the displacement and stress within the unit cell can be recovered.

Elastocapillary and limited Plateau–Rayleigh instability of soft hydrogel fibers

Berkin Dortdivanlioglu

The University of Texas at Austin, Austin, TX 78712, USA
berkin@utexas.edu

Key Words: surface tension, hydrogel, fiber, isogeometric finite elements, subcritical, instability

To date, the mechanics of interfaces of soft solids, e.g., polymeric gels, remain elusive. In particular, the mechanical properties of the bulk gel can differ from its boundary due to the fundamental role of surface tension and lower-dimensional energetics at length scales of nanometers to millimeters. From a theoretical perspective, classical continuum mechanics is size-independent and lacks a physical length scale. A characteristic length scale and size-dependent material response can be captured in continuum models by accounting for the energetic competition between the bulk gel and its boundary. This energetic competition, referred to as the elasto-capillary effect, plays a vital role in cavitation, soft composites, wetting on soft substrates, adhesive failure, and pattern formations such as beading, creasing, and wrinkling.

A fundamental challenge in understanding the behaviors of soft materials at small scales is the emergent instabilities due to complex elastocapillary stresses, e.g., the recently observed Plateau–Rayleigh (P–R) instability at soft gels. In *liquid* P–R instabilities, the surface tension overwhelms cylindrical columns and causes global undulations with a well-defined wavelength. However, the bulk elasticity will resist the capillary forces, playing a limiting role in *solid* P–R instabilities. The competition between capillary and bulk energies results in cylinders-on-a-string morphology in soft gels compared to spherical bead formations in liquid columns. This contribution aims to quantify the solid-surface competition and assess the highly nonlinear post-instability regime in soft solids at small scales.

The key focus of this presentation is to develop a computational framework modeling solid P–R instabilities using a surface-enhanced isogeometric finite element technique. First, we will show that the solid P-R instability is mainly a subcritical (discontinuous) bifurcation, which requires the development of path-following methods for gels to track stable and unstable equilibrium paths. Next, equipped with an arc-length-type nonlinear solution procedure, we study both the onset and the post-instability behaviors. We present numerical results illustrating the full evolution of P–R instability, observed in recent experiments with millimeter-scale hydrogel filaments. Our findings show that the soft cylinders form two distinct radii connected by a transition region with a finite width. Importantly, we show that the cylinders-on-string formations in hydrogels are highly tunable by controlling the applied stretch, residual stresses, and the characteristic length scale. The proposed methodology provides a robust computational foundation to elucidate elastocapillary instabilities in soft hydrogel fibers.

On wet coefficient of restitution of particles: a DNS study

Mehdi Jangi[1*], Niklas Adio[2] and Christopher Windows-Yule[2]

[1]School of Engineering, University of Birmingham, Edgbaston, Birmingham, B15 2TT, m.jangi@bham.ac.uk

[2]School of Chemical Engineering, University of Birmingham, Edgbaston, Birmingham, B15 2TT,

Key Words: *Coefficient of restitution, wet particles, DNS*

Global behaviour of wet granular flows is predominantly controlled by the exchange rates between particles and the carrier fluids at the microscopic levels. Therefore, accurate predictions of the macroscopic behaviour of the flow depend on the sub-models used to model the particle motions and their inner interactions. Among other parameters, the so-called "Coefficient of Restitution" (COR), defined as the ratio of the rebounding velocity to the impact velocity in a binary impact, is crucial as it directly impacts the nature of particle-particle interactions and the trajectory of particles in the flow, hence, the rates of mixing, and the energy dissipation in the system. While COR of dry impacts has been relatively well established, the problem of wet impacts and the effects of liquid bridging on the COR is still at the early stage of the investigations, see [1] and references therein. It appears that unlike a dry impact, which is essentially characterised by the impact force through mechanical properties of the particles and the impact velocity, a wet impact is far more complex, including cohesive [2], viscous and interfacial forces [3], and is currently an unknown function of the mechanical and surface properties of the particles, impact velocity, transport properties of the bridging liquid, intensity of the wetting, etc. [4].

In this paper, for the first time, we present fully resolved unsteady and multidimensional numerical simulations for wet impacts, using a new in-house DNS code that employs hybrid Levelset-VOF [4] combined with ghost-cell moving immersed boundary method. This enables fixed equidistance cartesian grids which in turn maximises the computational accuracy and maintains the CPU times at the minimum level. based on based on the. A series of simulations based on the experiments of Gollwitzer et al. [5] is carried out to computationally reproduce the wet COR of spherical glass particles impinging a wet planar surface. Time evolutions of the wave formations and liquid bridging are presented. The contributions of viscous and interfacial forces are calculated by calculating the time history of viscous dissipation and interfacial surface energies as a function of the thickness of the wetting liquid, diameters of the sphere and the impact velocity. COR for each case is calculated and compared with experimental data. Results are collectively discussed and the role of wetting on the COR is theorised.

Design optimization of single phase metamaterial for elastic wave bandgap: graph theory and genetic algorithm based approach

Nitish Kumar, Anuj Joshi, Aniket Waghmare, and Siladitya Pal
Department of Mechanical and Industrial Engineering, Indian Institute of Technology Roorkee, India

Abstract

Phononic metamaterials provide unconventional and unusual approaches to control the sub-wavelength elastic waves. In particular, locally resonant metamaterials (LRMs) attract great attention due to their potential applications as vibration isolation, low-frequency noise insulators, wave filtering, seismic wave mitigation, etc. It exhibits spectral gaps in the frequency range of two orders of magnitude lower than ones resulting from Bragg's scattering mechanism. Nevertheless, the formation of wide bandgaps in LRMs essentially requires the complex manipulation of multiple phases leading to difficulty in their fabrication. In order to overcome that problem, single-phase metamaterials with multiple bandgaps have been evolved in recent years. Although few attempts are made employing single-phase lattice structure to extract the wide bandgap; obtaining optimized configuration for the desired frequency bandgap through multiple parametric investigations is a challenging task. Therefore, the goal of the present study is to develop a numerical scheme for optimization of the single-phase lattice structure for desired frequency bandgap in the sonic range.

In this work, we provide a computationally efficient modification of the structure with predefined symmetry for tailorable bandgap. In particular, a graph theory-based approach will be used to represent the minimalistic unit of the lattice structure. Further, Analyzing the desired symmetric operations, the unit cells will be generated. Subsequently, connectedness upon boolean operation (addition and subtraction of edges) within the lattice is efficiently obtained. In order to achieve the optimized configuration GA based algorithm is performed. We adopt the beam element-based simulation framework for the extraction of dispersion response. Moreover, a more accurate evaluation of dispersion is obtained through the finite element procedure with the solid element. Consequently, we will also illustrate the mechanism of bandgap formation by addressing the local resonances with the vibration mode shapes. Then, the experimental investigation will be performed to validate the numerically calculated bandgap for optimized configuration. The present scheme will provide a numerical framework for the generation of optimized periodic units of single-phase metamaterials for the desired bandgap.

Metamaterials parameter determination by means of an asymptotic homogenization applied in the finite element method

Bilen Emek Abali[1]*

[1] Uppsala University, Department of Materials Science and Engineering, Uppsala, Sweden,
bilenemek@abali.org, http://bilenemek.abali.org

Key Words: Metamaterials, Strain gradient theory, Finite element method, Homogenization

Different length-scales are fused together in additive manufacturing. For example a feature is called "infill ratio," where structure's weight is reduced by replacing the bulk with a periodic lattice substructure. A typical example is a grid or hexagonal infill, in this way, the weight but also the stiffness is reduced. Such a porous structure is technically a structure with a substructure that is known as metamaterial. We know that such metamaterials may be modeled by a generalized method. One possibility is strain gradient theory. In addition to the classical stiffness parameters, substructure related parameters emerge. Their determination is challenging.

The newly emerged parameters are substructure related. Hence, technically, by a given substructure, a homogenization method allows us to determine them. Based on asymptotic homogenization [1] a new formalism is applied in [2]. This procedure computes all effective material parameters in metamaterials by using a representative volume element incorporating the substructure. The computational procedure by means of finite element method (FEM) is developed with the aid of open-source packages. A brief explanation of the formalism, verification of the procedure, and examples will be given in this talk.

Key Words: *Abnormal grain growth, Grain boundary properties, Phase-field model, HPC*

Grain growth phenomena are ubiquitously encountered in the engineering of polycrystalline materials. In particular, abnormal grain growth, through which a few grains undergo preferential growth, is of great technological importance because it plays a decisive role in the development of high-performance materials including textured materials and single crystals. As a promising model for analytically describing abnormal grain growth, the mean-field theory proposed by Humphreys [1] is well known. Assuming that the abnormal growth of a particular grain is induced by its size advantage and the nonuniformity in grain boundary properties (energy and mobility), the mean-field theory enables the abnormal grain growth behaviors to be expressed as a function of only three parameters: the size ratio, boundary energy ratio, and mobility ratio between the particular grain and its surrounding matrix grains. However, the validity of this theory is not yet tested in detail, which is largely due to the difficulties in experiments for ideal model systems and the limited computational scales and accuracies employed in conventional simulation studies.
Our previous studies (e.g., Ref. [2]) have developed a large-scale simulation method for grain growth phenomena based on the phase-field modelling and parallel graphics-processing unit computing. In this study, we apply the developed method to abnormal grain growth and elucidate the validity of the mean-field theory via systematic two-dimensional and three-dimensional simulations on greatly enlarged scales with several hundreds of thousands of grains. The multi-phase-field model [3] is employed as the numerical model, enabling accurate treatment of polycrystalline grain boundary migration under the conditions of nonuniform grain boundary properties. A series of grain growth simulations are performed while varying the initial size ratio, boundary energy ratio, and mobility ratio of a particular grain and matrix grains. Detailed comparisons of the simulated results and theoretical predictions demonstrate that the abnormal grain growth behaviors (i.e., whether or not the abnormal growth occurs and the limiting size that can be reached by an abnormally growing grain) is well described by the mean-field theory.

Key Words: *Phase-Field Model, Solid-State Sintering, Thermodynamical Consistency, Free Energy Analysis*

Manufacturing materials by sintering for high-performance applications with tailored properties requires a deep understanding of the underlying microstructure evolution process. The Phase-Field method has been widely employed to model the microstructure evolution during the solid-state sintering process incorporating surface diffusion, grain boundary diffusion, and volume diffusion. An analysis of the well-known Phase-Field model in [1] is performed and shows that the free energy form employed in [1] may artificially introduce pores in solid grain boundaries where no pores exist initially, which is thermodynamically inconsistent. Additionally, the ratio of surface energy over grain boundary energy significantly affects this pore-generation artifact. Inspired by the work in [1, 2], a novel Phase-Field model is proposed to ensure thermodynamical consistency [3]. It is shown analytically and numerically that the artificial pore generation phenomenon is removed in the proposed model.

Key Words: *Static recrystallization, Multi-phase-field method, Data assimilation*

The formability of aluminum alloys depends on their crystallographic textures. The textures are typically formed through static recrystallization that occurs during annealing. Hence, to produce aluminum alloys with superior formability, it is necessary to accurately predict static recrystallization and resultant texture formations. However, the mechanism of static recrystallization is still unclear and, therefore, intensive studies are widely undertaken to elucidate the recrystallization processes.

In experimentally observing static recrystallization, EBSD analysis is usually employed. However, it is difficult to reveal the whole picture of static recrystallization using EBSD analysis because it cannot observe the internal structures of metallic samples such as three-dimensional grain boundary configurations. Therefore, numerical simulation, which can analyse three-dimensional structures, is becoming common as a promising tool for the recrystallization study. In particular, the multi-phase-field (MPF) method is frequently used for simulating static recrystallization because the method allows for accurately reproducing polycrystalline microstructure evolutions. However, detailed data on the state variables and physical properties (e.g. stored energy) used in the MPF model is still not available due to the difficulty in their experimental measurement. On the other hand, data assimilation, which is a method for estimating unknown parameters in a numerical simulation by integrating observation data into the simulation, has attracted attentions as a means of improving simulation accuracy. It is expected that the accuracy of MPF recrystallization simulation can be improved by estimating the unknown parameter values via data assimilation. However, previous studies applying data assimilation to the MPF model [1,2] have focused only on simple curvature-driven grain growth, and the application to MPF recrystallization simulation is not yet attempted.

The purpose of this study is to estimate the state variables and physical properties such as stored energy by applying data assimilation to the MPF model of static recrystallization. Furthermore, we aim to elucidate the mechanism of static recrystallization by realizing highly accurate MPF recrystallization simulation. For this purpose, in-situ EBSD observation for static recrystallization of industrial pure aluminum was carried out to obtain observation data for data assimilation. We then estimated the state variables and physical properties included in the MPF recrystallization model by data assimilation using the in-situ observation results.

m1623036@edu.kit.ac.jp, sakane@kit.ac.jp, takaki@kit.ac.jp

Key Words: *Solidification, Convection, Dendrite, Phase-field Lattice Boltzmann Method, Data Assimilation*

Accurately predicting the formation process of solidification microstructures is critical for high-quality casting products. Recently, large-scale phase-field lattice Boltzmann simulations [1] and in-situ observations using time-resolved X-ray tomography [2] are performed to accurately elucidate the formation process of solidification microstructures. However, even such state-of-the-art technologies have major shortcomings, such as the lack of data on alloy material properties for simulations, and spatiotemporal resolution in observations.

Combining numerical simulations and experimental observations using data assimilation is a promising strategy for overcoming these drawbacks to enable highly accurate predictions of solidification microstructures. While data assimilation has been applied to elucidate some dendritic solidification processes, to the best of our knowledge, it has not yet been applied to dendritic solidification with melt convection.

In this study, we develop a data assimilation system using the phase-field lattice Boltzmann method [3] for predicting dendritic solidification with melt convection for the first time. The validity of the developed data assimilation system is confirmed through twin experiments for dendrite growth with forced convection, natural convection, and sedimentation of a solid grain.

Numerical simulations and experimental observations have made significant contributions to understanding the details of dendrite growth in alloy solidification. With the increase in recent computer speed, data science that enables integration of numerical simulations and experimental observations is attracting attention as the most promising approach. It is expected to overcome such conventional problems as low spatiotemporal resolution and limited information from experimental observations, as well as a lack of known material properties for the numerical simulations.

Yamanaka et al. [1, 2] first employed the data assimilation and phase-field method for the dendrite growth problem. Ohno et al. [3] proposed a method to infer interfacial properties of a pure alloy using data assimilation integrating molecular dynamics and phase-field simulations. In this study, we developed a data assimilation system combining three-dimensional (3D) simulations using the phase-field method [4] with time-resolved in situ 2D imaging using synchrotron radiation X-rays [5]. This was applied to dendrite growth during directional solidification of a binary alloy. Dendrites have a 3D structure, though the 2D imaging was conducted for a thin film sample. Thus, we performed an efficient 3D phase-field simulation using only the region immediately adjacent to the dendrite tip, as 3D simulations for the entire domain of the 2D imaging are challenging even now from the computational cost viewpoint. The developed data assimilation system was verified through numerical experiments, also referred to as twin experiments. Finally, we applied the data assimilation system to the 2D imaging of dendrite growth of an Fe-Si alloy.

DMC-BO: Efficient Data Assimilation Method using Bayesian Optimization for Phase-field Simulation of Solid-state Sintering

Akimitsu Ishii[1*], Akinori Yamanaka[1] Eisuke Miyoshi[1] and Akiyasu Yamamoto[1]

[1] Tokyo University of Agriculture and Technology, 2-24-16, Naka-cho, Koganei, Tokyo, 184-8588, Japan, a-yamana@cc.tuat.ac.jp

Key Words: *Phase-field method, Data assimilation, Bayesian optimization, Solid-state sintering*

Phase-field (PF) method is used for a powerful numerical simulation methodology to analyze microstructural evolutions during solid-state sintering. In order to quantitatively predict the microstructural evolutions by the PF simulations, accurate material parameters are required. However, many material parameters related to sintered materials, such as polycrystalline bulk superconducting materials, are unknown and immeasurable. On the other hand, cutting-edge experimental techniques (e.g., X-ray computed tomography) have realized the three-dimensional (3D) in-situ observation of microstructural evolution during the solid-state sintering [1, 2]. Therefore, recently, data assimilation (DA) has attracted attentions to estimate unknown material parameters from experimental data. DA has been developed for a computational technique that enables estimations of unobservable states and unknown material parameters by integrating time-series experimental data with the numerical simulation results based on Bayesian inference. In the previous study [3], particle shape, grain boundary distribution, and multiple material parameters were simultaneously estimated by applying the ensemble-based four-dimensional variational (En4DVar) DA method to a 3D PF simulation of solid-state sintering. Although En4DVar can estimate states and material parameters with high accuracy, it has a great challenge in computational cost. In order to overcome this challenge, in this study, we have developed a new DA method named DMC-BO [4]. DMC-BO uses Bayesian optimization (BO) to minimize the cost function which represents a misfit between simulation results and experimental data. DMC-BO is easy to implement in various simulation models because DMC-BO does not require the complicated calculations for deriving adjoint model [5]. Moreover, using BO reduces the computational cost for the minimization of the cost function. In order to validate DMC-BO, we conducted numerical experiments called twin experiments. The results demonstrate that DMC-BO is capable of simultaneously estimating the states and material parameters at less than half of the computational cost for En4DVar. Furthermore, the accuracy of the estimsted material parameters are reasonable for predicting the evolutions of the particle shape and grain boundary with high accuracy.

Sintering is an important process for many technical applications, but a full understanding still eludes the scientific community. Simulations are one key component of furthering this understanding by resolving the process from the atomistic to the mesoscopic process scale. Within the mesoscopic scale, the phase-field method has recently been used to simulate the sintering process by various authors. The employed models can vary drastically, even though the same process should be simulated, with no clear consensus on which model is the more correct one. In order to determine which models should be used and further developed, molecular dynamics simulations are employed to establish qualitative rules of motion during sintering. Following the determination of the rules, several published phase-field models and modified versions of these are tested for their compliance with these rules. Based on these results a phase-field model is developed for investigating the effects of sintering temperature and packing geometry in large-scale three-dimensional phase-field simulations. These simulations will be used to explain the enhanced densification observed in novel sintering techniques such as flash sintering.

Multi-phase-field Modeling and Simulation of Sintering

Sintered products are usually manufactured by filling powdered material into a mold, followed by the pressurization and heating of the material. Sintering is advantageous over casting in that complex-shaped products can be easily produced without melting the material. However, the products fabricated by sintering have lower strength than those fabricated by other working methods because the removal of pores is difficult. To address this issue and optimize the sintering process, systematic evaluations by a numerical simulation are indispensable. However, there are no well-established numerical methods to predict the microstructures formed during sintering with a high accuracy.

The phase-field method is the most powerful and accurate method for predicting the material structures at a meso scale. Wang [1] first applied the phase-field method to the sintering phenomena, based on which many sintering phase-field simulations have been carried out [2, 3]. However, it is difficult to accurately introduce surface/grain boundary properties, such as energy and mobility, as well as their anisotropy, into the model [1]. In addition, we need to reconsider the tensional force acting between two neighboring grains, which causes the rigid body motion.

In this study, we developed a sintering model based on the multi-phase-field model with a double-obstacle potential [4, 5], which can most accurately introduce the anisotropy of surface/grain boundary properties. Further, we developed a parallel computing code using multiple graphics processing units to accelerate the three-dimensional sintering simulations with numerous particles.

Multiscale modeling and simulation of the crystallization, thermal sintering and thermo-mechanical response of semi-crystalline polymers

Amine Bahloul[1,2], Issam Doghri[1], Laurent Adam[2]

[1] Université catholique de Louvain, iMMC, Louvain-la-Neuve, Belgium

Key Words: multiscale modeling, semi-crystalline polymers

An enhanced phase field model was developed for the numerical simulation of crystallization in semicrystalline polymers [1]. As with other models, it is based on coupling the heat equation with the Allen-Cahn equation, which is derived from the Gibbs-Thomson solid-liquid interface equation. Starting from the nucleation of spherulites, existing phase field models can simulate their evolution in a surrounding liquid and separate the amorphous and crystalline phases. However, the predictions of the morphological characteristics of the spherulites remain qualitative only. Moreover, the predicted spherulite evolution as a function of crystallization temperature is not consistent with experimental results. In our work, existing phase field models were enhanced in order to obtain experimentally consistent results. We target these characteristics to make them quantitative: spherulite growth, crystal morphology, and crystalline rate in spherulite. We show the importance of modeling the dependence of the model's parameters with respect to crystallization temperature, because, if assumed constants, the predicted results are not consistent with polymers physics. The model is numerically implemented using the finite difference method so that 2D and 3D simulation results are presented and compared to experimental data, illustrating the quantitative adequacy of the predictions with experimental evidence. Full-field micromechanical simulations were conducted on the microstructures generated by the enhanced phase field model in order to predict the effective mechanical properties [2]. A Fast Fourier Transform (FFT) method with periodic boundary conditions is used. Care is taken to obtain representative volume elements (RVEs) by computing the number of subcells in each spherulite and the number of spherulite nucleations in each RVE. Numerical FFT predictions of elastic properties for a range of crystallinity ratios are validated against experimental data and compared to simpler composite inclusion models. Finite element simulations of thermal shrinkage are also shown. We are currently extending the material description to a more realistic viscoelastic-viscoplastic model. The crystalline lamellae follow an orthotropic viscoplastic model based on the activation of slip systems, while the amorphous phase is (nonlinear) viscoelastic. Some properties can be identified directly while others are calibrated from reverse engineering. The procedure and its capabilities are illustrated for some polymers for which experimental data is available (e.g., stress-strain curves at different strain rates). A micromechanical model is currently being developed in order to predict the densification during a SLS (selected laser sintering) additive manufacturing process, and its impact on the mechanical response. All the models have been implemented in a research version of the Digimat software (from Hexagon Manufacturing Intelligence Division).

Key Words: *Phase-field Simulation, Solute Segregation, Dislocation Pinning, Mg-based Alloys*

To achieve wide applications of Mg-based alloys for structural components, extensive efforts have been made to increase the strength and formability of the alloys. It has been reported that an aging heat treatment of a pre-strained Mg-based alloy induces the solute segregation at dislocation, leading to the significant increase in the flow stress of the alloy (bake-hardening phenomenon) [1]. In this study, we performed phase-field simulations to obtain precise knowledge about the solute segregation behaviour and its effect on the pinning force of dislocation in Mg–Al–Ca–Zn system.

Elastic field of an edge dislocation was considered, and the solute diffusion driven by the inhomogeneity of elastic and chemical potentials in Mg–0.7Al–0.3Ca–0.3Zn (at.%) alloy was calculated by solving the Cahn–Hilliard equation. The simulation conditions of aging temperature and aging time were changed in the ranges of T = 413–473 K and t = 0–10^4 s, respectively. The simulated solute distribution was used to estimate the pinning force of dislocation; the dislocation was artificially displaced along the slip plane with fixing the solute distribution, and the elastic energy was calculated as a function of the dislocation displacement. The maximum gradient of the elastic energy–displacement curve was assumed as the pinning force of dislocation [2].

Segregation of Al, Ca and Zn near the dislocation core was observed in the phase-field simulation. Ca first segregated at the opposite side of the extra half plane, and subsequently, Zn and Al segregated at the side of the extra half plane. These results are reasonable in terms of the difference in the diffusion coefficients of solute atoms and the reduction of elastic energy derived from the dislocation and solute atoms. The segregation amount increased with increasing aging temperature and aging time, resulting in the increase in the pinning force of dislocation. Our simulation results show that the condition of aging heat treatment in a previous study (443 K, 1200 s) [1] is appropriate to achieve the bake-hardening effect derived from the solute segregation at dislocation.

Key Words: *Phase-field Simulation, Grain Boundary Segregation, Solute Drag, CALPHAD*

Overall properties of polycrystalline materials depend on the properties of individual crystal grains, distribution of crystallographic orientations (texture), and the properties of grain boundaries (GB). In various alloys, solute segregation to GB often occurs, leading to GB fracture and/or changing GB migration rate. Some theoretical models including phase-field models have been developed for predicting GB segregation [1,2]. However, past studies have mainly focused on the solute segregation to stationary/moving GB in binary systems, and there are few studies on the solute segregation to moving GB in multicomponent systems despite its practical importance.

In this study, the phase-field model for predicting solute segregation to moving GB in binary system developed by Cha *et al*. [2] was extended to the model for multicomponent systems. GB was treated as a distinguishable phase, and the Gibbs energy of liquid phase was substituted for the GB phase considering amorphous nature of GB. With a coordinate system that moves with GB, the movement of GB at a constant velocity was considered by adding a constant flux term to the diffusion equation of solute. Under this condition, one-dimensional steady-state profile of concentration and its drag effect on GB (solute-drag effect) was calculated. The Gibbs energy was directly extracted from existing CALPHAD databases using the Thermo-calc software [3].

As a case study, GB segregation and solute-drag effect in dilute magnesium alloys at 623 K were evaluated in Mg–Al–Zn, Mg–Zn–Ca and Mg–Al–Ca systems. The concentration profile around GB and the resultant solute-drag force were successfully obtained as a function of GB velocity. The simulation results show that the segregation behaviour in multicomponent systems is closely related not only to solute-solvent interaction but also to solute-solute interaction.

Key Words: *Solidification, Phase-field model, Computational fluid dynamics, Data assimilation*

The mechanical properties of alloys largely depend on their microstructures that are formed through solidification and subsequent metallurgical phenomena. Because the solidified microstructures in alloys are typically determined by the dendritic growth of crystals, it is necessary to accurately understand the dendrite growth for predicting the microstructural evolutions. Although direct experimental observations of growing dendrites have been reported in previous studies[1], it is difficult to measure the states of solidification such as solute concentration and flow velocity in a liquid phase from the experiments. Therefore, numerical simulations of dendrite growth using the phase-field method have been widely performed. However, many parameters involved in the phase-field models of alloy solidification are unknown. Our research group has proposed data assimilation methodologies to estimate the unknown parameters of the phase-field models from experimental data[2-6]. Specifically, the previous study[5] applied the local ensemble transform Kalman filter (LETKF), which is one of the most computationally effective methods for sequential data assimilation, to the phase-field simulations of alloy solidification. In this study, this LETKF-based phase-field model (LETKF-PF model) is coupled with the Navier-Stokes (NS) equation to account for the fluid flow in a liquid phase. Further, we perform numerical experiments to validate the estimation of the material parameters and the states including solute concentration and velocity fields in a Fe-C-Mn alloy. The numerical experiment results demonstrate that the present LETKF-QPF-NS model can simultaneously estimate the solute concentration field, velocity field, solute diffusion coefficient, and interfacial energy from the morphological data of a growing dendrite.

Key Words: K-Feldspar dissolution, Etch-pits, Phase-field method, Numerical simulation

Estimating the porosity and permeability of rocks is a necessary component of reservoir modeling. Feldspar dissolution is a widespread phenomenon in clastic bedrock reservoirs located in petroleum-bearing zones, affecting porosity, permeability, and thus reservoir quality [1]. We adopt a phase-field model to the dissolution of K-feldspar (Orthoclase) in the present work [2]. This leads in the formation and growth of etch pits, which vary in size and shape depending on the crystallographic orientation of the feldspar grains. We begin by calibrating the anisotropic model parameters to account for anisotropy in the surface energy and particle detachment kinetics at the feldspar-water interface. Calibration is accomplished by simulating the free growth of an etch pit in a single feldspar crystal and digitally replicating the formation and relative rates of the pits' different faces based on earlier experimental and numerical findings [3]. Following that, the calibrated model is used to simulate etch pitting in a variety of digital multi-grain packs with varied proportions of quartz and feldspar grains, analogous to sandstones. Furthermore, the digital grain packs are used to perform computational fluid dynamics analysis on the progressively pitted quartz-feldspar sandstones to determine their permeabilities. The proposed model is capable of recreating natural pit morphologies. The numerical data sets created are evaluated to determine the effect of etch pitting on the permeability, porosity, and mineral composition of sandstones, which is experimentally improbable or time consuming. Finally, we show the model's capabilities using novel post-processing and visualization techniques.

The meso-failure of ceramsite lightweight aggregate concrete based on the phase-field model

Jichang Wang[1,2*], Xiaoming Guo[1]

[1] Jiangsu Key Laboratory of Engineering Mechanics, School of Civil Engineering, Southeast University, Nanjing 210096, China, jichangw@163.com; xmguo@seu.edu.cn
[2] Department of Civil and Environmental Engineering, National University of Singapore, (S)117576, Singapore

Key Words: *Lightweight concrete, Meso-failure, Phase-field, ABAQUS*

A phase-field model is developed to describe the meso-failure process of lightweight concrete containing expanded clay ceramsite aggregates. The phase-field model is applied to the meso-failure process of lightweight concrete by the ABAQUS subroutine user-defined element (UEL). The improved staggered iteration scheme with a one-pass procedure is used to alternately solve the coupling equations. In addition, the typical three-phase characteristics of lightweight concrete are incorporated into the phase-field model by generating mesostructures with mortar matrix, ceramsite aggregate, and interfacial transition zones through an automatic generation and placement program. The accuracy and effectiveness of the model in the cracking process of lightweight concrete meso-model are verified by the uniaxial tensile, three-point bending, and four-point bending common failures and mixed-mode failures of the meso-model of lightweight concrete are analyzed. The mesoscopic crack paths of the lightweight concrete calculated by the phase-field model are consistent with the transgranular fracture mode obtained by our test. At the same time, the crack appearance is similar to the results obtained by DIC, and the force-deflection curve is in good agreement with the experimental data in our test. The results show that the cracks of lightweight concrete specimens mainly occur in the ceramsite aggregates with weak strength, especially in the ceramsite aggregates with large particle sizes. The distribution of the ceramsite aggregates has a great influence on the peak load of the force-deflection curves, especially aggregates with large particle diameters. With the increase of the volume fraction of aggregate, the slope and peak load of the force-deflection curve decrease gradually, the bearing capacity of lightweight concrete specimens decreases, and the possibility of crack branching and coalescence decreases in the process of crack propagation. These examples show that the phase-field model can well capture the meso-failure process of lightweight concrete.

Key Words: QM/MM, Graphene deposited Silicon solar cells, micro-cracks, multi-physics, electrical conductivity

Silicon is an abundant material on earth and is the primary choice in manufacturing photovoltaic solar cells. The fabrication of thin pristine Silicon solar cells involves several steps. As a result, defects like dislocations, micro-cracks and voids are unavoidable, and they tend to grow in the presence of multiple fields. Defects hinder the motion of charges. As a result, the charges will be accumulated around the defects [1, 2], which leads to the release of energy through recombination effects. On the other hand, the presence of defects alters the band gap in Silicon. Various authors studied the influence of mechanical and thermal loads on the band gap of Silicon [3, 4, 5] and reported that the band gap either changes or shifts from indirect to direct. The electrical conductivity improves when the bandgap decreases and vice-versa.

In this study, a multi-scale, multi-field analysis is performed using the QMMM package of Large-scale Atomic Molecular Massively Parallel Simulator (LAMMPS). The main objective is to study the performance characteristics of Graphene deposited Silicon solar cells in the presence of cracks. Initial cracks are created by deleting the bonds between the atoms on the crack surface. Furthermore, the cracks are opened by specifying a mechanical load in the form of tensile displacement, whereas, the thermal load is prescribed in terms of heat rate. During the entire simulation a quantum domain around the crack tip is considered to accurately estimate the electronic charge density of the atoms around the crack tip, and hence the electrical conductivity.

A Novel Atomistic-Continuum Coupling Method for Amorphous Polymers at Finite Temperature

Sankha Subhra Aditya[1*] and Samit Roy[1]

[1] The University of Alabama, Box 870280, Tuscaloosa, AL 35487-0280, USA, sroy@eng.ua.edu

Key Words: *Multiscale modelling, concurrent coupling, atomistic modelling, finite element method, amorphous materials, finite temperature*

In this work, a new simulation technique is presented for the concurrent mechanical coupling of particle and continuum domains at finite temperatures with potential application to fracture simulation in polymer nanocomposite materials. The coupling methodology is based on the Arlequin framework as proposed by Ben Dhia et al. for particle-continuum coupling in [1] and utilizes the concept of so-called anchor points for transmitting information between the two domains as developed in [2]. A bridging domain is defined wherein the particle and continuum domains overlap and forces and displacements may be transmitted. The present work draws upon the idea of grouping particles in the bridging domain to form Interface Volume Cells (IVC) as presented in [3]. These groups of atoms are then, in a spatially and temporarily averaged sense, connected by springs to respective anchor points in the continuum domain. This combination of techniques results in a new formulation that circumvents the need to connect continuum anchor points to individual particles, while benefitting from the inherent stability of a tunable spring-based load transfer mechanism.

In the present work, the particle domain is modelled using Molecular Dynamics (MD) in an all-atom representation at a temperature of 300 K and the continuum domain is modelled using the Finite Element Method (FEM). The two domains are solved iteratively until convergence is achieved for a given load state. Due to the continuum and particle domain time scales being vastly different, the FEM domain is solved statically, while the MD domain is run dynamically. A static uniaxial tension test is simulated using a three-dimensional block of EPON-862 resin, that is 85% crosslinked with curing agent DETDA. The applied loading is initially maintained within the linear elastic regime for model verification. Quantities such as stresses, Young's modulus, Poisson's ratio, and reaction forces are analyzed for convergence in the bridging domain and verified against a similar specimen modelled fully with FEM using experimental data available for EPON-862. After model verification in the linear elastic range, the loading is increased to simulate damage evolution and failure localization in the MD domain, in order to verify the post-yield behavior of the coupled model.

A multiscale continuum model is developed to describe the defect structures in crystalline material such as FCC metals. The interface structure for twist, tilt and misfit grain boundaries are described by the dislocation network. The model incorporates both the anisotropy elasticity of each grain in crystalline materials and the molecular dynamics calculation informed interaction between two bulks, i.e., the nonlinear generalized stacking-fault energy. The equilibrium structures are obtained from the numerical simulations of the force balance differential equations. We apply this approach to determine the structure and energetics of twist, tilt and general grain boundaries. We also investigated the dislocation structure in heterogeneous crystalline material. Our model agrees well with the atomistic results. An analytical description is developed based on the obtained structural features.

Towards a robust multi-scale numerical modeling of the impact behavior of woven materials using equivalent microscopic fibers

Key Words: *Finite elements, Dry woven fabrics, Ballistic impact, Multi-scale modelling, Equivalent fiber.*

A multi-scale modelling of the mechanical behavior of a dry 2D woven fabric subjected to a ballistic impact is developed in a combination between a mesoscopic description for the secondary yarns (not in direct contact with the projectile) and a microscopic description for the primary yarns (in direct contact with the projectile) in order to take into account the important fiber/fiber and fiber/projectile interactions in the impact zone. However, it should be noted that at the microscopic scale, a yarn is composed of approximately 400 fibers, the inclusion of which can significantly increase the computation time. For this, we have opted to introduce the notion of an "equivalent fiber" corresponding to 10 fibers. This proposed approach conducted to use 42 equivalent fibers in total to model a yarn. The effectiveness of this multi-scale strategy has been demonstrated by a comparison in terms of projectile velocity and projectile reactions, as well as degradation mechanisms of this multi-scale model with those obtained in the case of a complete mesoscopic modelling that were well validated with experimental data.

A polarization-based multiplicative approach for modeling electrostrictive polymers

Astrid Pechstein[1*], Alexander Humer[1] and Michael Krommer[1]

[1] Institute of Technical Mechanics, Johannes Kepler University Linz, Altenberger Straße 69, 4040 Linz, Austria. {astrid.pechstein|alexander.humer|michael.krommer}@jku.at

Key Words: Finite strain electro-elasticity, electrostrictive material modeling, mixed finite elements

Electro-active polymers play an important role in today's engineering applications. Modeling and simulation of these materials, that respond to electrical stimuli by large-scale mechanical deformations, has been an active field of research during the last decade. Contrary to piezoelectric ceramics, that mostly operate in the linear range at a predefined polarization state, the electro-mechancial coupling in polymers is through higher order effects.

For the description of the deformation state, commonly displacement and deformation gradient are used. The electric field is the second independent quantity in many models. Thermodynamic potentials such as the free energy relate these independent fields to secondary fields: (total) stress and dielectric displacement. These secondary fields satisfy local equilbrium and Gauss' law. Different approaches for modeling electrostrictive behavior have been considered by various authors. A common approach is the prescription of field-dependent electric permittivities. An alternative is the introduction of a multiplicative splitting of the deformation gradient into an electric and a mechanic part, $\mathbf{F} = \mathbf{F}_{el}\mathbf{F}_{me}$ [1]. Multiplicative splittings are well-known from the modeling of visco-elastic electro-active polymers.

When such a multiplicative splitting is introduced to model electrostriction, the electric part of the deformation gradient is usually assumed as depending on the electric field, $\mathbf{F}_{el} = \mathbf{F}_{el}(\vec{e})$. However, in this case saturation of electrostrictive straining for higher electric fields that is observed in experiments [2] is not contained in the model. Therefore, we propose a different approach, where the electric part of the deformation gradient is considered depending on the electric polarization. In our models and also finite element implementations, we use dielectric displacement and polarization as primary unknowns, such that the electric field is seen as a secondary field. This way, by modeling saturation of the electric polarization, saturation of electric straining is a direct consequence. Additionally, Gauss' law of zero charges is satisfied exactly. A stable mixed finite element scheme for various element types is provided for (nearly) incompressible electrostrictive polymers.

Modeling and numerical simulations of MEMS shutter devices

Dominik Mayrhofer*, Manfred Kaltenbacher†

TU Graz, Inffeldgasse 18, 8010 Graz, Austria, *dominik.mayrhofer@tugraz.at
†manfred.kaltenbacher@tugraz.at

Key Words: ADSR, MEMS, ALE, linearized flow equations

We investigate the acoustic behaviour of Micro-Electro-Mechanical-Systems (MEMS) with a focus on shutter devices. These shutter devices can be used for a new method of sound generation – which we call Advanced Digital Sound Reconstruction (ADSR) – where a redirection mechanism for sound pulses is incorporated [1]. With the help of this redirection mechanism, sound pulses can be generated which are superimposed to form an audio signal.
At MEMS-scales viscous effects can play a major role regarding sound transmission. Therefore, we utilize the linearized flow equations in time domain in order to solve for the acoustic pressure while incorporating effects caused by viscous boundary layers. Furthermore, the movement of the shutter itself contributes to the overall generated sound in a negative manner. Since the generation of the sound pulses is in the ultra sound range, the generated noise by the shutter might lead to adverse effects on the human body [2]. Hence, modeling the shutter noise and understanding its generation process can help to improve the design. To model the noise generated by the shutter, we apply the arbitrary Lagrangian-Eulerian (ALE) framework to the linearized flow equations to be able to compute the noise generation on the moving geometry. The geometry update itself is governed by an artificial quasi-static mechanical problem which is solved in each step to get the new element deformation [3].
Assuming that the impact of the acoustic pressure is negligible, a simple forward coupling from the quasi-static mesh-smoothing to the the linearized flow equations is employed. Furthermore, we use a direct coupling approach to couple the acoustic wave equation to the linearized flow equations. The final coupled system is then used to characterize the impact of the shutter movement on the overall system behaviour of a certain embodiment.

Modeling viscous and thermal effects in acoustic actuators

Florian Toth[1,*] **and Hamideh Hassanpour Guilvaiee**[1]

[1] Institute of Mechanics and Mechatronics, TU Wien, Getreidemarkt 9, 1060 Vienna, Austria
[*] florian.toth@tuwien.ac.at

Key Words: Mechatronics, Multiphysics Problems, Acoustics, MEMS

Viscous and thermal effects are usually neglected when investigating acoustic phenomena. This is admissible if the corresponding boundary layer thickness remains small compared to the relevant problem dimensions. For air at standard atmospheric conditions the viscous boundary layer thickness is about 70 µm at a frequency of 1 kHz, which makes viscous effects relevant in important novel applications like micro perforated panels (MPPs) and acoustic actuators based on MEMS technology. A similar argument holds for the inclusion of thermal effects.

Several approaches exist to model viscous and thermal effects: Of course the flow field can be described by the full Navier Stokes equations, which need to be coupled to the flexible solid at the common interface. The resulting set of equations may be solved by, several numerical schemes, all of which share a large computational effort often rendering these methods unfeasible, e.g. for industrial applications. Another common approach is to linearise the compressible flow equations for small (acoustic) disturbances. Especially for cases without stationary background flow, this is often admissible, and the resulting equations can be solved employing the finite element method (FEM) [2]. Another approach is to employ an acoustic formulation in therms of the acoustic wave equation to model the flow field, and incorporate viscous and thermal effects in the boundary layers via an impedance type boundary condition [1]. This approach is computationally cheap, but is only applicable when the modeling assumptions of fully developed boundary layers are fulfilled.

Based on the example of a piezoelectric MEMS actuator, we demonstrate the importance of modeling viscous and thermal effects, with respect to the accuracy of the resulting acoustic field. We use a FEM formulation of the linearised compressible flow equations implemented in the open source finite element code openCFS [3]. We show how non-conforming interfaces can be used to couple solid and fluid domains without requiring conforming mesh at the interface. Finally, we investigate what assumptions in terms of mesh size, approximation order, and fluid domain size are suitable to minimize the numerical effort while maintaining acceptable accuracy.

Key Words: *Asphalt, Mesoscale, Visco-elasto-plasticity, Creep*

To describe the mechanical behaviour of asphalts it is mandatory to numerically reproduce their internal structure, namely the location of bitumen and aggregates and voids. Subsequently, it is necessary to develop a sound mechanical prediction of creep, through a correct evaluation of the stress concentration among the inclusions and the voids within the domain of interest [1]. The mechanical behaviour at medium-to-long-term of asphalt is studied in the present work in a 3D mesoscale approach, by explicitly modelling the composite material as a cluster of aggregates (the coarse fraction is considered, for computational reasons) and bitumen surrounding them. The internal structure of an asphalt sample can be reproduced via a random disposition of inclusions, satisfying a given grading curve and a known volume fraction, as proposed in [2], when more sophisticated techniques are not available.
In agreement with recent viscoelastic formulations [3, 4] a novel visco-elasto-plastic constitutive model has been developed, where the viscoelasticity is accounted for via a fractional formulation, i.e. through a parabolic-dashpot-based mechanical representation. The subsequent non-integer order differential model is treated with the Grünwald definition of fractional derivatives. Long term effects have been carried out under different monotonic and cyclic load conditions, based on some relevant experimental tests. The model itself accounts for a better understanding of the inclusions interaction within asphalt under different compressive external loads.

Key Words: *Visco-elasto-plasticity, Damage, Cyclic loadings, Concrete*

A novel 3D comprehensive visco-elasto-plasto damage constitutive model of concrete is proposed to analyse the behaviour of concrete under long-term and cyclic loadings. This model combines the visco-elasticy and plasticity theories together with damage mechanics. The paper aims at providing an efficient model capable of predicting all the hysteretic characteristics of concrete material during cyclic loadings, taking into account time-dependent effects. The visco-elastic part is modeled within the framework of the linear visco-elasticity theory. The creep function is evaluated via the B3 model by Bažant and Baweja [1], and implemented with the exponential algorithm. The modified Menetrey-Willam [2, 3] pressure-dependent yield surface and a nonassociative flow rule are used for the plastic formulation of the model. The damage part of the model considers two exponential damage parameters, one in tension and one in compression, accounting for a realistic description of the transition from tensile to compressive failure [4]. The proposed model is calibrated and compared with uniaxial and multiaxial experimental tests.

Key Words: *Solid state batteries; Polycrystalline Cathode; Interfacial Fracture; Bulk fracture; Phase field fracture; Diffused interface model*

All solid-state batteries (ASSBs) are promising candidates for "next-generation batteries" toward higher energy density, better thermal stability, and reduced flammability. The major obstacles for attaining the high energy density are the occurrence of chemical and mechanical degradations within the different components of ASSBs. In particular, the initiation and evolution of fracture within the grains, grain boundaries, electrolyte and electrode-electrolyte interfaces can cause capacity fade due to the loss of contact, reduction of material strength and transport properties under cyclic charge/discharge process. Stabilizing the ASSBs and extending their lifetime call for a high-fidelity electro-chemo-mechanical computational model that could be used for exploring the physical mechanisms and for identifying promising remedies through informed synthesis or operating conditions. In that context, a thermodynamically consistent multi-physics modelling framework is developed. In particular, it interprets the coupled electro-chemo-mechanical interactions in a battery cell, which includes the 3-D polycrystalline NMC cathode particle, sulfide based solid electrolyte phases, grain boundaries, and the electrode-electrolyte interfaces. For more realistic simulations, a secondary cathode particle is statistically reconstructed using the electron back scattering diffraction (EBSD) data and synthetic grain-architecture algorithm. In order to consider the initiation and propagation of crack within grains, grain boundaries, electrolyte and electrolyte-electrode interfaces, a regular phase-field fracture variable has been employed. A diffused phase field parameters have been adopted to define the transition of mechanical properties between the grains, grain boundaries, electrolyte, and electrolyte-electrode interfaces. Apart from incorporating the anisotropic material properties, the concentration dependent transport and mechanical properties have been considered. It is worth mentioning that the present model has been implemented in the open-source finite element (FE) package MOOSE for solving three state-variables: concentration, displacement, and phase-field damage parameter. Various parametric studies will be performed to explore the role of primary particle or grain sizes, secondary particle sizes, charge rates, interface properties and elastic modulus of the solid-electrolyte to correlate between the chemo-mechanical behavior and evolution of fracture on the electrochemical response of batteries. The present findings from the model offer predictive insights for designing the battery cell with reduced fracture evolution and enhanced electrochemical performance. Finally, the proposed model has been validated with the experimentally obtained characteristics of chemo-mechanical degradation.

Simulation of Piezoelectric Mechanism to Suppress Dendrite Growth

Wei Lu

Department of Mechanical Engineering, and Department of Materials Science and Engineering,
University of Michigan, Ann Arbor, MI 48109, USA
weilu@umich.edu, https://lu.engin.umich.edu/

Key Words: *Dendrite, Battery, Multiphysics, Modeling*

On immersing two lithium metal electrodes in a solution containing lithium salt and applying a voltage, lithium metal will deposit on the electrode connected to the lower voltage. This process is known as electrodeposition. It has been widely observed that under moderate currents, lithium ions do not deposit to a flat surface but rather spontaneously form sharp needle shapes known as dendrites. Dendrite formation is a major barrier for realizing the lithium metal battery, which not only causes capacity loss but also leads to internal short circuit and safety hazard [1].

We report a discovery that the use of a soft piezoelectric film as separator can effectively suppress the formation of lithium dendrite and stabilize the lithium surface during electrodeposition system [2, 3]. When the film is deformed by any local protrusion because of surface instability of the deposited lithium, a local piezoelectric overpotential is generated to suppress lithium deposition on the protrusion. We have established a theory that integrates electrochemistry, piezoelectricity and mechanics. We developed multiphysics computations to simulate dendrite growth in contact with a piezoelectric film. We find that the dendrite-suppression capability is over 6 orders stronger than the limit of mechanical blocking by any separators or solid-state electrolytes. Simulations show that the mechanism ensures deposition to form a flat surface even if the initial substrate surface has significant protrusions, suggesting its robustness and effectiveness against manufacturing defects. We show that the mechanism is so strong that even a weak piezoelectric material is highly effective, opening up a wide range of materials.

Key Words: *multiscale preconditioner, VFP-Ampére, adaptive mesh, conservative discretization.*

We discuss a fully-implicit iterative solver for the Vlasov-Fokker-Planck—Ampère (VFPA) system with one configuration-space dimension and two velocity-space dimensions (1D-2V). The VFPA system couples a multispecies kinetic plasma description to the electrostatic electric field. The purpose of this work is to enable efficient, high fidelity, fully kinetic simulations of weakly- to moderately-coupled high-energy-density plasmas with an arbitrary number of species, particularly in regimes relevant to inertial confinement fusion (ICF). For many applications of interest (e.g., ICF implosions) the VFPA system exhibits large separation of numerical and physical scales in time and space, in particular due to the plasma frequency, fast electron motion, and electron collisions [1]. This numerical stiffness is addressed here by iterative implicit timestepping, accelerated by a high-order/low-order (HOLO) strategy (essentially a multiscale moment-based preconditioning scheme [2]). The scheme also employs an adaptive mesh strategy in physical and velocity space [3], in which the velocity space of each species is analytically rescaled and shifted by its spatially and temporally varying thermal speed and bulk flow, respectively; a moving mesh is used in the configuration space that allows tracking features with sharp spatial gradients, such as shocks and material interfaces. Further, conservation of mass, momentum, and energy, together with Gauss' law, are discretely preserved – commensurately with the iterative nonlinear relative tolerance – through a Lagrange-multiplier-like approach using nonlinear constraint functions [1, 4]. We demonstrate the effectiveness and accuracy of the algorithm with several benchmark problems of varying complexity, including a fully kinetic collisional plasma shock in planar geometry.

Key Words: Monte Carlo, Gaussian, Coulomb Collisions, Particle-in-Cell

Coulomb collisions in particle simulations for weakly coupled plasmas are typically modeled by Monte-Carlo (MC) methods [1]. One of the main disadvantages of MC is the timestep accuracy constraint $\nu\Delta t \ll 1$ to resolve the collision frequency (ν) [2]. The constraint becomes extremely stringent for self-collisions in the presence of high-Z species, and for inter-species collisions with large mass disparities, rendering such simulations impractical. To overcome these difficulties, we explore a hybrid MC-Gaussian model for hybrid kinetic-fluid simulations. Specifically, we devise a collisional algorithm that leverages Maxwellians (i.e. isotropic Gaussians) [4] for both highly collisional kinetic species and fluid ones. We perform Gaussian-particle collisions using the Lemons method [3], which we have improved by more careful treatment of low-relative-speed particles. We extend the standard TA method for particle-particle collisions with arbitrary particle weights without losing conservation properties. The hybrid MC-Gaussian method is strictly conservative and is orders of magnitude faster than straight MC. We will illustrate the accuracy and performance of the proposed method with several examples of varying complexity, including relaxation and transport problems.

Accelerating Radiation Transfer with the Variable Eddington Factor Method

Samuel Olivier

University of California, Berkeley, USA, solivier@berkeley.edu

Key Words: radiation transport, kinetic effects, discontinuous Galerkin

The numerical simulation of radiative transfer is typically the dominant cost in the radiation-magneto-hydrodynamics codes used to model high energy density physics experiments such as the National Ignition Facility (NIF) at Lawrence Livermore National Lab. In fact, radiative transfer often accounts for 90% of the runtime and memory usage in simulations of NIF. This expense arises from the need for the accuracy of a kinetic model of the radiation field in these problems. A moment-based, reduced description of the kinetic equation allows the moment equations to couple directly to the other multiphysics components isolating the expensive inversion of the kinetic equation from stiff multiphysics.

The Variable Eddington Factor (VEF) method [1], also known as Quasidiffusion [2], is one such moment-based radiation transport algorithm. In VEF, the moment equations closed with nonlinear functionals computed from a discrete kinetic solution are iteratively coupled to the kinetic equation. Since these closures are weak functions of the solution, simple iterative schemes, such as fixed-point iteration, can converge rapidly. However, the low regularity of the closures and the unusual structure of the closed moment equations make leveraging existing discretization and linear solver technology difficult. Existing methods either rely on expensive and un-scalable preconditioners or leave solvers as future work. Without efficient solvers, VEF does not compete with traditional radiative transfer methods and is thus rarely used in practice.

In this talk, the unified analysis of Discontinuous Galerkin methods developed for elliptic problems presented in [3] is extended to the closed moment equations. The resulting VEF method is shown to have high-order accuracy in space, compatibility with high-order (curved) meshes, and efficient and scalable preconditioned iterative solvers. The method is tested on a challenging radiative transfer proxy problem and shown to scale to 1152 processors.

Key Words: Boltzmann Collision Operator, Reduced Order Models

With the emergence of novel applications of rarefied gas flows in hypersonic and space flights and microscopic flows, there is an increased need for simulation tools capable of handling complex flow geometries and of accurately predicting complex physics of the flows of non-continuum gas. The Boltzmann equation is believed to be the most accurate model of non-continuum gas. However, a major challenge continues to be the evaluation of the multifold integral describing the effect of molecular collisions.

We consider application of reduced order models (ROMs) to accelerating evaluation of the Boltzmann collision operator. To construct the ROM, a collection of solutions to the problem of spatially homogeneous relaxation of sums of two Gaussian densities are computed. Approximation spaces for the ROMs are formed by a subset of singular vectors of the solution data matrix [2]. Two cases of ROMs are considered. The first ROM results from a straightforward Galerkin discretization of the spatially homogeneous Boltzmann equation using a truncated basis of the singular vectors. The model approximates solutions to the Boltzmann equation accurately during early stages of relaxation. However, it suffers from presence of ROM residuals at later stages and exhibits polynomially growing modes for large ROM sizes. The second ROM evolves the difference between the solution and the steady state. The truncated singular vectors are orthogonalized to the steady state and modified locally to enforce zero density, momentum, and temperature moments. Exponential damping of ROM residuals is added to the model to enforce physical steady state solution. Solutions obtained by the second ROM are asymptotically stable in time and provide accurate approximations to solutions of the Boltzmann equation. Complexity for both models is $O(K^3)$ where K is the size of the ROM basis. For the considered class of problems, the models result in up to three orders of magnitude acceleration as compared to the $O(M^2)$ nodal discontinuous Galerkin (DG) discretization of [1], where M is the total number of velocity points.

Key Words: Multi-fluid plasma models, Continuum kinetic plasma models, Hybrid plasma modeling, Discontinuous Galerkin, Plasma sheath, Magnetized Kelvin-Helmholtz instability

A numerical method is developed for coupling a multi-species kinetic plasma model with a 5N-moment multi-fluid plasma model. The simulation domain is decomposed such that the local conditions satisfy the corresponding plasma model's region of validity. The method allows for hybrid simulations by formulating each model as a set of conservation laws and using a continuum numerical method to solve each model's governing equations in the subdomains of the decomposed domain. The models are coupled through fluxes across subdomain interfaces. Two methods are explored for the formulation of the fluxes that can be self-consistently represented by both plasma models. One method allows for flux calculations consistent with the 5N-moment multi-fluid plasma model and assumes thermodynamic equilibrium within each species of the kinetic plasma model. The second method ensures conservation of the distribution function as well as mass, momentum, and energy by formulating the fluxes using a composite underlying distribution function at the subdomain interfaces. The methods are compared in 1D1V simulations of a double rarefaction wave and a plasma sheath using the WARPXM framework, which solves each model using the discontinuous Galerkin finite element method. Both methods for formulating the fluxes perform well as the subdomain interface distribution function approaches a Maxwellian, with the consistent method being more robust to larger deviations. A simulation of the magnetized Kelvin-Helmholtz instability in 2D2V is also performed using the consistent method, which demonstrates the potential of the domain-decomposed hybrid method in facilitating speedup and reduction in required computational resources for high-fidelity plasma simulations, allowing for the investigation of problems that are beyond current capabilities. The coupling method is also used to study the lower hybrid drift instability, which is important to describing transport properties such as resistivity in Z-pinch plasmas.

Low-rank Methods for Radiation Transport Calculations

Zhuogang Peng[1*], **Ryan G. McClarren**[1]

[1] University of Notre Dame, Notre Dame, IN, USA
zpeng5@nd.edu, rmcclarr@nd.edu

Key Words: Dynamical Low-rank Approximation; Radiative Transfer; High-order/low-order (HOLO)

The numerical solution of the radiation transport equation (RTE) is challenging due to the high computational costs and the large memory requirements caused by the high-dimensional phase space. Here we detail an attempt to reduce the memory required, and computational cost of solving RTE by applying the dynamical low-rank (DLR) method [1, 2], where a memory savings of about an order of magnitude without sacrificing accuracy is observed. The DLR approximation is an efficient technique to approximate the solution to time-dependent matrix differential equations. The desired approximation has three components similar to factors in singular value decomposition (SVD), and each of them is solved by integrating the matrix differential equation projected onto the tangent space of the low-rank manifold.

This talk presents our recent work that builds on the established DLR method and aims to enable low-rank schemes for practical radiation transport applications. We propose a high-order/low-order (HOLO) algorithm to overcome the conservation issues in the low-rank scheme by solving a low-order equation with closure terms computed via a high-order solution calculated using DLR [3]. With the properly chosen rank, the high-order solution well approximates the closure term, and the low-order solution can be used to correct the conservation bias in the DLR evolution. This improvement goes a long way to making the method robust enough for a variety of physics applications.

We also introduce a low-rank scheme with discrete ordinate discretization in angle (SN method) [4]. This low-rank-SN system allows for an efficient algorithm called "transport sweep," which is highly desirable in computation. The derived low-rank SN equations can be cast into a triangular form in the same way as standard iteration techniques.

[*] watanabe.tomohiko@nagoya-u.jp

Key Words: *Fusion, Plasma, Kinetic dynamics, IMEX, Numerical scheme*

Collisionless dynamics of numerous numbers of charged particles, that is, *plasma*, provides common subjects and interests in studies of fusion, space, and astrophysical phenomena, where nonlinear evolution of the one-body distribution function of particles in the phase space needs to be solved together with fluctuations of the electromagnetic fields. In case with a background magnetic field, the charged particle motions are strongly anisotropic, and the field-aligned dynamics of electrons and electromagnetic fields govern the fastest time scales of the system after taking an average of the gyro-motion. However, in applications of fusion, space, and astrophysical plasmas, many interests are devoted to slower time scales than the parallel dynamics, such as the plasma turbulence and transport or fluid-like phenomena in a macro-scale. In other words, the fast parallel dynamics of electrons and electromagnetic fields are bottlenecks for an efficient time-integration of the plasma kinetic equation in a low-frequency regime.

In order to find a breakthrough in numerical schemes for the drift kinetic or gyrokinetic simulations of magnetized plasma, we have developed the moment extract method (MEM) [1] which decouples the zeroth and first order moment equations from the kinetic equation of electrons, preserving the full drift kinetic dynamics. The derived set of equations can be efficiently solved by means of an implicit-explicit (IMEX) scheme [2] when the phase speed of the electromagnetic (dispersive Alfven) wave exceeds the electron speed. The new scheme can relax the Courant limit for the drift kinetic simulation in the low plasma pressure limit.

In application to higher pressure plasma, where the electron speed may restrict the time-step size, we have applied the MEM to the semi-Lagrangian scheme developed for solving the Vlasov equation. The novel method demonstrates relaxation of the time step size both for the low and high plasma pressure cases, and improves numerical stability of the semi-Lagrangian scheme applied to the electromagnetic (Alfvenic) regime.

Key Words: *Local coupling, Convergence stability, Operator splitting, Error Estimate, Multiphysics Problems*

Complex models involving numerous coupled physical processes create substantial computational challenge. This paper introduces a solver algorithm that maintains a locally fully coupled system in the subdomains in which individual physical process interacts with other processes strongly. Meanwhile, the solutions in the other regions are obtained in a decoupled fashion. The fully coupled regions are updated dynamically by either different timesteps or iterations.

Global coupling of multiple physics generally results in systems with large number of unknowns that are computationally unfeasible. In response, decoupling algorithms, such as three-way coupling of flow and geomechanics in porous media (Lu and Wheeler 2020), are introduced. Although alleviating the computational load, certain decoupling strategies commonly results in stability issues (Mikelić and Wheeler 2013), especially for nonlinear problems and sometimes encounters divergence during the solution process. The local coupling strategy applies error estimators to determine the strength of interaction between the physical processes in subdomains. By maintaining the system in fully coupled form within critical regions, the stability issue from the decoupling strategies is avoided while the computational load is significantly reduced as compared to a global coupling strategy.

The solver algorithm is tested with multiphase flow in porous media problem and provides up to 75% reduction is computation time. Additionally, such method could be applied to more complicated multiphysics problems such as fluid-driven fracture propagation (Lee, Wheeler and Wick 2016). Fully coupling of flow and mechanics in regions with crack propagation could facilitate the solution process. Previous method that decouples the two processes completely has caused significant increase in iterations.

Multiscale model learning

Eric Chung[1]

[1] Department of Mathematics, The Chinese University of Hong Kong, Hong Kong,
tschung@math.cuhk.edu.hk

Key Words: Multiscale problems, multiscale methods, machine learning

We design novel multi-layer neural networks for multiscale simulations of flows taking into account the observed data and physical modeling concepts. Our approaches use deep learning concepts combined with local multiscale model reduction methodologies to predict flow dynamics. Using reduced-order model concepts is important for constructing robust deep learning architectures since the reduced-order models provide fewer degrees of freedom. Flow dynamics can be thought of as multi-layer networks. More precisely, the solution at the time instant n+1 depends on the solution at the time instant n and input parameters, such as permeability fields, forcing terms, and initial conditions. One can regard the solution as a multi-layer network, where each layer, in general, is a nonlinear forward map and the number of layers relates to the internal time steps. We will rely on rigorous model reduction concepts to define unknowns and connections for each layer. In each layer, our reduced-order models will provide a forward map, which will be modified (?trained?) using available data. It is critical to use reduced-order models for this purpose, which will identify the regions of influence and the appropriate number of variables. Because of the lack of available data, the training will be supplemented with computational data as needed. We will also use deep learning algorithms to train the elements of the reduced model discrete system. The work is partially supported by the Hong Kong RGC General Research Fund (Project numbers 14304719 and 14302620) and CUHK Faculty of Science Direct Grant 2020-21.

A micromechanical approach for porous elasto-plastic hardening materials based on coupling full-field and mean-field homogenization methods

Chiheb Naili[1], **Issam Doghri**[1*]

[1] Université catholique de Louvain, Institute of Mechanics, Materials and civil Engineering (iMMC)

Key Words: Porous plasticity, Modeling, Computational simulation, Homogenization

This work proposes an original and rather simple micromechanical approach to deal with the case of an elasto-plastic hardening matrix material containing circular or spherical cavities, in 2D and 3D respectively. The matrix can also be reinforced with solid particles. The purpose of the approach is to combine the high accuracy of full-field homogenization with the very low computational cost of mean-field homogenizatioon.

The strategy consists in coupling full-field (FE) homogenization for single cavity problems with Mori-Tanaka mean field homogenization at the representative volume element (RVE) level. First, a simple FE homogenization is conducted for a single cavity model (for both 2D and 3D cases) in order to get the homogenized stress-strain of an equivalent material called S. Then the actual porous RVE is alternatively modeled as being madee of solid spheres (or disks) of the actual matrix material embedded inside the material S. The volume fractions are determined from a maximum packing argument. Results were compared afterwards to reference simulations conducted on RVEs for 2D and 3D models. Very good agreement was found.

Next, for a particle-reinforced porous RVE (a three-phase material) the two-level strategy previously advocated for linear elastic materials by Naili et al.(2020) was extended to elasto-plasticity. Again, it was found that the proposed method exhibits very good accuracy.

The micromechanical strategy was successfully implemented and validated for the secant formulation of elasto-plasticity, which is restricted to monotonic and proportional lmoadings. Current work consists in extending the proposal to an incremental formulation of elasto-plasticity able to handle general loading histories.

Key Words: Elastodynamic homogenization, Dispersion relation, Willis theory, Bloch waves, Clustering Analysis

This article presents a reduced-order method for the elastodynamic homogenization of periodic composites. With the help of Bloch-wave expansion and Green function, the Lippmann-Schwinger equations relating the dynamic field variable tensors of strain, velocity, stress and linear momentum are obtained. Then the constitutive relation of the averaged dynamic field tensors and the dispersion relation between frequency and wave vector in Willis theory are calculated directly. Using the data compression algorithm, k-means clustering, we decompose computational domain into clusters of possibly disjoint cells. The Lippmann-Schwinger equations are then discretized and solved efficiently. Numerical tests for 1D layered composites and 3D particle-reinforced composites verify the effectiveness and efficiency of the reduced-order method.

Keywords: *Curvature, Size effect, Nanoparticle, Molecular dynamics*

It is widely acknowledged that size effect on material properties exists at small scales. The influence of size on the strength of micro- and nanoparticles, which are the raw material for particle-based additive manufacturing technology, has drawn great attention but the universal conclusion still requires more efforts. Among all the methods, the nano-indentation carried out with molecular dynamics simulation is effective and attractive to investigate material properties and mechanisms.

In this presentation, nano-particles are examined with spherical indenters and we focus on the influences of particle size and indenter size simultaneously. All the simulations are run with Lammps code on the Explorer 100 high-performance platform of Tsinghua University. Particle radii and indenter radii covering a wide range ranges are examined to investigate their independent and joint influences. The ratio between the particle size and the indenter size is found to be an essential influential factor on the indentation curves, which categorizes the type of mechanical response of particles. When the ratio is fixed, the first yielding point increases monotonically with the size increasing, which implies that small particles may be easier to accommodate plastic deformation. Our results can be extended to more complex problems such as impact of micro particles on the substrate.

Data-driven Explicit Structural Topology Optimization with Hyperelastic Materials

Key Words: *Data-driven, Topology Optimization, Finite Deformation, Hyperelastic*

Based on the constitutive theory, in the present work, a data-driven structural topology optimization method, which can solve the explicit topology optimization problem of the continuum structure with hyperelastic materials under finite deformation by only using uniaxial and biaxial experimental data, is developed. In this optimization problem, the aim is to minimize the compliance of the structure under the constraint of material volume. In addition, the degree of freedom removal technique is adopted to overcome the non-convergence problem of finite element analysis caused by weak material elements in the optimization process. Finally, some classic numerical examples are given to verify the effectiveness and stability of the proposed optimization algorithm.

Key Words: *Material Law; Viscoelastic; Data-driven; Convolutional Neural Network*

In this work, a new data-driven method for building viscoelastic material law is proposed by combining characteristics of viscoelasticity theory and machine learning. Convolutional neural network (CNN) is used appropriately in this method to reduce the required amount of training data for machine learning. With only a small amount of data, the proposed method can learn the classical viscoelastic models described by a series of exponentials known as the Prony series. For a given displacement load, the trained model can predict the material response at the unknown moment. Results show that the present method can also predict the material law for complex microstructured materials with components described by another viscoelastic or elastic material models. Even under a complex cyclic loading, the accuracy of material behavior prediction can still be guaranteed. Limitation of the proposed approach is also discussed.

Key Words: *Porous material, Cluster Minimum Complementary Energy, FEM-Cluster Based Analysis, Reconstruct the singular interaction matrix.*

The efficient prediction of nonlinear effective properties of heterogeneous materials is of great significance for their optimal utilization and material design. Based on the idea of data-driven clustering, Cheng et al. [1] proposed the FEM-Cluster based Analysis (FCA) to efficiently predict the nonlinear mechanical properties of various composite materials. FCA is different from the traditional computational micromechanics method which introduces reference materials and solves the discrete Lippmann-Schwinger (L-S) equation. In the FCA, the boundary value problem of the Representative Volume Element (RVE) is defined on a unit cell of the actual material and the interaction matrix can be regarded as the discrete Green operator, whose column vectors constitute the basis of the cluster self-equilibrium stress space. The step by step nonlinear properties prediction is carried out on the cluster-based reduced order model in the cluster self-equilibrium stress space by minimizing cluster complementary energy [2].
One of the recent developments of FCA is to apply the method for porous materials. We construct the reduced order model with no low modulus material filling in pores which was often seen in the methods such as the Fast Fourier Transform (FFT) to avoid numerical instability and convergence difficulties. It is interesting to discover the existence of the best low rank cluster self-equilibrium stress subspace, in which the projection of the interaction matrix reduces the cluster averaging errors and dimension of the reduced order model simultaneously. A reconstruction algorithm is proposed to define the best low rank cluster self-equilibrium stress subspace and construct the singular interaction matrix. Further, the unknown strain of the pore domain in the data-driven clustering reduced order method makes the Hill-Mandel inapplicable, the direct energy equivalence principle instead of the mean field theory is used to predict the effective properties of porous materials. Numerical examples are provided to illustrate the effectiveness and efficiency of this method [3]. Finally, the best low rank subspace and its related full stress vectors are being explored for the damage analysis of heterogeneous materials.

Key Words: steel-concrete interface, corrosion, composite structures, homogenization

Finite element analyses of reinforced concrete with the steel rebars can be particularly useful to evaluate the remaining life of aged structures accurately. However, the presence of ribs along the rebar length introduces geometric complexities which cannot be modelled explicitly for use in finite element analysis. To alleviate this drawback, a homogenized model of the interface consisting of rib geometry around the bar surface along with the concrete keys has been developed in this work. The asymptotic expansion homogenization method [1] is applied to evaluate the effective properties of the deformed bar-concrete interface. Owing to the axial periodicity of the rib geometry and concrete keys, the theory has been modified to incorporate the uni-directional two-scale response at the interface. An axially periodic Representative Volume Element (RVE) incorporating the geometric details of ribs along with concrete keys has been constructed. RVE analysis has been performed with appropriate strain boundary conditions applicable for a pullout test. A non-linear analysis has been used for capturing the equivalent maximum shear strength of the interface prior to failure. The results from RVE analysis has been used to obtain the equivalent homogenized stiffnesses of the interface and the maximum shear strength which have been further used in the cohesive zone model [2] which is based on Mohr-Coulomb material model. The developed homogenized interface model is validated from experimental pullout test results of deformed bars and would be further used to study the effect of corrosion on performance of structures.

Key Words: *Thermal Load Identification, Multiple Estimation Strategies, Neural Network*

Identifying external thermal loads with limited measurement responses is important for the two-compartment structure, which is widely used in spacecrafts, when the real-time measurements of various loadings cannot be obtained directly. However, the measurement information from the limited number of sensors leads to an ill-posedness problem of inverse load identification. In this paper, A multiple estimation strategies based on neural network is considered, which narrows the solution domain of the problem step by step. The common issue of most of the literatures is the utilization of a single neural network to address this problem. In the multiple estimation, a combination of classification neural network and regression neural network has been proposed by author and it aims to gradually estimate the position and magnitude of thermal loads, respectively. A detailed description of multiple estimation strategies, neural network algorithm, data acquisition, and validation examples is presented, in order to show the effectiveness and feasibility of the proposed load identification method.

Key Words: *Multibody dynamic simulation, Absolute nodal coordinate formulation, Finite element method, FE^2 method*

During the last few decades, flexible multibody dynamics has been widely used as an important theoretical basis. It has been frequently combined and used with the floating frame formulation (FFRF), which uses a local coordinate with an absolute coordinate. Within FFRF, the mass matrix will become nonlinear since the centrifugal force and Coriolis force are used due to the use of the local coordinate. On the other hand, the absolute nodal coordinate formulation (ANCF) has been developed recently to deal with the large deflection[1]. Within ANCF, the nodal coordinate of the element are described in the global inertial coordinate, so that the centrifugal force and Coriolis force may not appear but internal force may become significantly nonlinear.

Recently, investigation on ANCF related to biomechanics, space web, and soft machines has been actively conducted. Material characterization in the fields such as biomechanics, satellites and soft-machine machinery will require more sophisticated analysis to account for complexity of the relevant construction. However, further improvement in the constitutive relationship was required in the previous studies. Components used in those fields require use of the composite material, which are light and has improved strength and stiffness. Analysis upon the composite materials commonly requires multiscale modelling approach. And, a famous one of the multiscale modeling methods is finite element,[2] a versatile computational homogenization approach that is generally applicable for many material [2].

In this paper, multiscale modeling approach for a geometric nonlinear situation is suggested by using ANCF-FE^2 approach. This framework will connect micromechanics directly to existing ANCF element. Compared to the existing FE,[2] ANCF will obtain the exact Jacobian of the equation of motion in a straightforward fashion by using the invariance of the mass matrix and Jacobian simplicity of the constraint equation, [3]. It will be also straightforward to linearize the formulation which may exhibit advantage regarding the geometrically nonlinear analysis. Several numerical examples will be presented in order to demonstrate benefit of the present formulation.

Key Words: Data-driven multiscale method, Structural-Genome-Driven, Multi-level finite element method

In the design and fabrication fields of composite structures, multiscale problems attract considerable attention recently, such as how to obtain macroscopic constitutive models and track microscopic deformations simultaneously. Conventional multiscale modeling approaches, such as the concurrent homogenization methods, can deal with the problems, at the cost of the extremely high computational expense. In the data era, data-driven multiscale methods provide possibilities for solving the problems [1]. In this paper, an efficient data-driven multiscale method for composite plates is developed based on the Structural-Genome-Driven (SGD) method [2]. Firstly, the generalized strain and stress are adopted to construct the penalty function of data-driven framework of plate. Then, the multi-level finite element method (FE^2) is applied to collect the multiscale structural genome data for the database construction of the composite plate. Numerous offline microscopic calculations are performed within Representative Volume Elements (RVEs) using computational homogenization. Finally, the structural genome database is used to drive the online data-driven computing, whose results are compared with those obtained via conventional approaches to verify the accuracy and the efficiency. Since the conventional simulation process is decoupled into the offline data preparation and the online computing, in which the structural elements are employed for the simulations, the efficiency of the proposed data-driven approach is highly improved compared to the conventional one.

Numerical Boundary Treatment for Shock Propagation in the Fractional KdV-Burgers Equation

Xinyi Guan[1], Qian Zhang[1] and Shaoqiang Tang[1]

[1] HEDPS and LTCS, College of Engineering, Peking University, Beijing 100871, China

Key Words: Fractional KdV-Burgers equation, Shock wave, Boundary treatment, Machine learning, Ridge regression

We have proposed a numerical boundary treatment for simulating shock propagation in the fractional KdV-Burgers equation, based on a machine learning strategy. Numerical boundary treatment is particularly challenging due to the nonlinear and global interaction among the fractional diffusion, convection and dispersion. We select a suitable number of boundary points and interior points, and correct the numerical value at the boundary ones by linear combination of those at the interior ones. The large set of parameters are trained from a numerical reference shock solution connecting the end states 1 and 0, by ridge regression. Numerical tests demonstrate that the boundary treatment is effective in reflection suppression, and preserves the correct shock speed even under perturbed initial profile. Furthermore, using the above parameters, we construct a modified boundary treatment to simulate a range of different end states, with effectiveness checked numerically.

Numerical study of Gas Tungsten Arc Welding (GTAW) of a thin austenitic steel structure using two approaches: equivalent heat source approach and simplified approach

H. Aberbache [1, 2], A. Mathieu[1], R. Bolot[1], L. Bleurvacq[1], A. Corolleur[2], F. Laurent[2]

[1]Laboratoire Interdisciplinaire Carnot de Bourgogne, UMR CNRS-6303,

Université de Bourgogne-Franche Comté, 12 rue de la Fonderie, 71200 Le Creusot, France

[2] Sté Métallurgique de Fontaine Française Route de Chazeuil, MAGYAR - SMFF, France

The aims of this study concerns the simulation of GTAW in the field of multi-materials structure. The major topic concerns the thickness reduction of the stainless-steel sheets in the structure. In order to get an equivalent mechanical resistance compared to conventional ones, a composite material (fiber + resin) is applied by windings operation, with the objective to build a lighter structure. In this context, a program of tests and numerical simulations was defined, in order to predict, in a robust way, the final deformations due to welding operations. A comparison between experience and simulations, integrating the thermal and mechanical phenomena occurring during GTAW of stainless steels is performed.

The experimental part of this work was based on instrumented GTA welding tests. As far as the in-situ instrumentation is concerned, it was carried out on 1 mm thick metal sheet. Instrumentation was mainly based on thermal measurements by K-type thermocouples, displacements and strain measurements obtained by Digital Image Correlation technics, as well as arc welding current and voltage measurements.

In addition, cross-sectional macrographs of the weld seam were captured, in order to identify an equivalent heat source, for this process and in a butt weld configuration.

Thermomechanical simulation were then performed by using the equivalent heat source approach, taking into account the history of elements, namely the changes from solid to liquid and liquid to solid states. These simulations also take into account the real geometry of the beads due to addition of a filler material in the GTA process.

Using this approach, satisfactory results were obtained for thermal calculations. For mechanical calculations, determination of the bending angle of the sheets due to welding operation are also satisfactory, but calculations of the global displacements and strains of the sheets need to be improved.

A simplified approach was developed in parallel in order to reduce the CPU time. This approach is mainly based on the following observation: deformations generated by welding operations appear after manufacturing of the seams. According to our calculations means, this approach is the only one possible today, at the scale of a complete structure due to calculation time limitation purpose. Its implementation on simple sheets has just been carried out in this work: it allows in fine to reproduce the observed deformations obtained by DIC measurements without falling back on transient thermomechanical simulations, which demands too long calculation time, considering the scale of a complete assembly of structure. This approach is therefore quite promising.

On the coupling of Data-Driven computing and Model-Driven computing for composite materials and structures

Jie Yang[1], Wei Huang[1], Qun Huang[1] and Heng Hu[1*],

Key Words: *Data-Driven, Model-Driven, Coupling, Composites*

Multiscale simulation methods for composite materials and structures have been intensively developed during the past decades. The balance between the computational efficiency and accuracy remains one of the main issues. Recently, the Data-Driven Computational Mechanics [1] (DDCM) opens a new route to achieve this balance. By directly embedding the constitutive data into mechanical simulations, it bypasses the empirical material constitutive modelling, thus reduces the related cost and modelling error. Obviously, the development of DDCM could be accelerated based on the fruitful achievements of Model-Driven Computational Mechanics (MDCM, which refers to the standard constitutive model-based simulations), such as model reduction techniques, homogenization methods, domain decomposition techniques, etc.

In this work, we will discuss two potential combinations between DDCM and MDCM: (1) the data-driven computational homogenization method, where the multilevel finite element technique [2] (FE^2) is applied to construct accurate constitutive database, and the distance-minimizing data-driven approach is employed to reduce the online computing time; and (2) a domain decomposition coupling technique between DDCM and MDCM [3], where DDCM is employed for the local region to avoid material modelling errors and uncertainties, whilst MDCM is applied to the remaining regions to benefit from its computational efficiency.

Key Words: *AMCs, Micro-Mechanics, RAE, RVE*

Aluminum matrix composites (AMC's) are composed of a ductile Aluminum matrix reinforced by stiff ceramic particles. AMC's, which are commonly manufactured using powder metallurgy, are highly attractive structural materials for the automobile and aerospace industries due to their high strength to weight ratio [1]. To improve the strength of the aluminum matrix, the use of ceramic particles composed of SiC, Al_2O_3, or B_4C is usually considered. TiB_2 is also a promising candidate for aluminum reinforcement. Nevertheless, while incorporating ceramic reinforcement to the aluminum matrix can result in increased yield and ultimate stress, it does not necessarily imply an increase in stiffness. The increase in AMC strength can be attributed to the localized stress fields among reinforcement particles, or the particles themselves acting as barriers for dislocation motion. On the other hand, the increase in stiffness depends on the load transfer between particles and matrix. The exact influence of the conditions of the particle-matrix interface on the effective elastic properties for such materials is still an open question.

In the present study a computational homogenization methodology is used to determine the effective elastic properties of AMC's by using both representative area elements (RAE) and representative volume elements (RVE). Simplified unit cell geometries were considered, as well as geometries constructed from micrographs. The first part of the study compared the effective elastic properties obtained for different particle volume fractions using RAE and RVE models. The second part focused on the influence of the particle-matrix interface conditions on the effective elastic properties in both tension and compression.

The study demonstrates that while RAE and RVE models produce similar estimations for the fully bonded condition, differences are obtained for the non-bonded case. It is also shown that increasing the volume fraction when the interface is weak reduces the effective elastic modulus and effective Poisson's ratio. The change in effective elastic properties is different in tension and compression, and can be correlated to differences in the mechanical interaction between the particles and the matrix. Compression experiments on Al-TiB_2 cylindrical specimens and ultrasonic testing for different particle volume fractions (0-15% TiB2) support the computational findings [2].

Viscoelastic-viscoplastic polymer composites: development and evaluation of the two dissimilar mean field homogenization models

Mohamed Haddad[1*], **Issam Doghri**[1]

[1] iMMC, Université Catholique de Louvain
Bâtiment Euler, 1348 Louvain-la-Neuve, Belgium
mohamed.haddad@uclouvain.be

Key Words: Micromechanics, Mean field Homogenization, Viscoelasticity-viscoplasticity

Materials are hierarchical in nature. Their macroscopic responses are strongly dependent to featured information at micro-scale. This multiscale nature of materials poses a continuing challenge in computational modeling of macroscopic structures.

This study proposes a micromechanical modeling of polymer composites with viscoelastic-viscoplastic (VE-VP) constituents. **Two mean field homogenization (MFH) models based on completely dissimilar theoretical approaches were developed within the infinitesimal strains framework** [1]. **The first approach is the incremental-secant method**. It relies on a fictitious unloading of the composite at the beginning of each time step. Then, a thermoelastic-like Linear Comparison Composite (LCC) is constructed from the computed residual state directly in the time domain. The method provides naturally isotropic per-phase incremental-secant operators for isotropic VE-VP constituents. It takes into account both the first and the second statistical moment estimates of the equivalent stress micro-field. **The second approach is the integral affine method**. It starts by linearizing the rates of viscoplastic (VP) strain and internal variables. The linearized constitutive equations are then recast in a hereditary integral format to which the Laplace-Carson (L-C) transform is applied. A thermoelastic-like LCC is built in the L-C domain, where MFH is carried out. Finally, the composite's response in the time domain is recovered by numerical inversions of L-C transforms. The method is able to overcome the issue of heterogeneous viscous stresses encountered by time domain MFH models.

The two proposed MFH formulations are able to handle non-monotonic, non-proportional and multi-axial loading histories. Their accuracy was assessed against full-field finite element (FE) results for different microstructures and loadings. **The computational cost of both methods is negligible compared to FE analyses**. Overall, **the incremental-secant approach is much simpler mathematically and numerically than the integral affine formulation, its accuracy ranges from acceptable to excellent**, and important improvements can be expected in the future by controlling the virtual unloading time increment.

Currently, the incremental secant model is being extended to the finite strain framework. The objective is to further consider strain softening and re-hardening of constitutive materials at large VP deformations.

The control of acoustic and elastic waves through metamaterial design has been an interesting subject with great potentials of various applications such as non-destructive evaluation of structural, biomedical devices [1], high-resolution imaging, radar and remote sensing. To date, there is still a lack of powerful and efficient design methodologies since the conventional optimization-based approaches suffer from the computation burdens in parameter search whenever a design query is made. In this study, a deep auto-encoder (DAE) [2] based approach is proposed to design the geometry of wave scatterers that satisfy the user-defined downstream pressure fields. The estimation of scatterer geometry is strengthened with the latent representations of the pressure fields learned by the DAE. Once the training is finished, given a target 2D pressure fields, the proposed approach achieves an accuracy of 99.91% on the testing data, and the inference efficiency is enhanced by a factor of 195, compared to the baseline reference implemented using the genetic algorithm. Furthermore, the generalization capability of the proposed network is validated through a dataset generated with new shapes of wave scatterers. Lastly, this study provides an insight into the interpretation of the convolution layers in the network [3]. Numerical simulations and design examples are presented to demonstrate the robustness of the proposed approach.

Key Words: *Metasurface, Elastic Wave, Generalized Snell's Law*

Elastic metamaterials, which have been an active research area in the last two decades, come from improving the high working frequencies of periodic structures. The frequencies which make the left-handed metamaterials casue the refracted waves to bend into a negative direction. Metasurface, which is a thin layer in subwavelength scale, manipulates waves through phase shifts. Instead of three-dimensional left-handed metamaterials, metasurfaces use simple planar designs to produce the same effect. The planar fabrication process is cost-effective in comparison to the manufacturing of the complex 3D metamaterials. Since Yu et al. [1] designed the V-antennas to demonstrate generalized Snell's Law, metasurfaces have been studied extensively. This study focuses on elastic waves. Through different elastic metasurface designs, anomoulus refractions and corresponding applications are achieved.

Key Words: *Material Design, Metamaterial, Bistability, Finite Element Method*

Metamaterials exhibit supernatural properties which cannot be realized with bulk materials owing to their periodic structures in order of nano-, micro-, or milli-meter. Lately, additive manufacturing (AM) technologies have been applied to the fabrication of metamaterials with cellular lattice structures which are specially designed unit cells exhibiting novel mechanical properties such as auxetic materials having negative Poisson's ratio. Recently, bistable metamaterials that can convert their geometry reversibly between two or more different stable or metastable configurations have been researched. From the similarity of the geometric transformation of these bistable metamaterials and phase transformation of crystalline materials, these metamaterials are called phase transformation cellular materials (PXCM) [1]. In our previous research, for the purpose of investigating the relationship between the geometric design and bistable property, we conducted a compression test for PXCMs in various geometry [2]. In the present study, for analysing the criteria for the phase transformation, the deformations of the bistable lattices have been analysed with finite element method (FEM), and the solution was compared to the experiment. The bistable structure is composed of sinusoidal curved beams, vertical straight beams which connect curved beams with each other, and horizontal straight beams which cross the vertical beams. The bistability is exhibited by a sinusoidal curved beam snapping through from the initial state to a different state [2]. We designed the bistable lattices with straight beams of various widths and investigated how the straight beams affect the bistability. Specimens were fabricated by material extrusion (MEX) with thermoplastic polyurethane (TPU). The deformation of the specimens was recorded with a video camera during loading and during the unloading process, and the behaviours were compared to FEA simulation. When the straight beams were thin, the deformed state was unstable and shape recovery similar to superelasticity occurred since because thin straight beams bent greatly and could not restrain the deformed state of the sinusoidal beam. On the other hand, when the straight beams were sufficiently thick, although the curved beams deformed greatly, the deflection of the straight beams were small, and the deformed state was stabilized. We are going to propose a method of designing a cell lattice structure which exhibit these behaviours according to the required characteristics.

Harnessing Distinct Deformation Modes of Auxetic Patterns for Tailoring Elastic Wave

Jeong Min Hur[1*] and Do-Nyun Kim[1]

[1] Seoul National University, 1 Gwanak-ro, Gwanak-gu, Seoul 08826, Republic of Korea,
hawkjym@snu.ac.kr and dnkim@snu.ac.kr

Key Words: *Auxetic, Elastic Wave, Bandgap, Disk Stiffness*

Auxetic metamaterial has a negative Poisson's ratio that expands laterally via a unique deformation mode induced by its internal geometry. Under shear, this metamaterial deforms similar to non-auxetic materials. This load-dependent deformation mode can be exploited to independently adjust structural properties in two different directions, for example, bending and torsional stiffness [1].

In this study, we introduce this concept to independently tailor elastic waves in two different modes, a flexural and torsional wave by adjusting their bandgap. To demonstrate it, a circular pipe structure with periodically arranged auxetic disks is considered. We designed auxetic disks with independently tuned torsional and radial stiffness in a wide range, validated by finite element analysis. The natural frequencies of each mode are then calculated, which determine the bandgap formation. The numerical measurements demonstrate that the elastic wave is prohibited to propagate in the bandgap, verifying that the wave propagation characteristics of two different modes can be independently tailored.

This work provides an integrated method that can independently design dynamic properties of two different modes which were inherently coupled, and has a potential to be applied in the field of vibration suppression and non-destructive testing.

Key Words: *Phase Transforming Cellular Material, bimetal, finite element method*

Typical Phase Transforming Cellular Material (PXCM) are bistable metamaterials that undergo large displacement and are associated with the change in their periodic internal structure when a compressive load above a certain level is applied causing buckling of the curved beam [1,2]. Due to the bistability, such a PXCM maintains the deformed shape even after unloading and recovers the original shape by reverse deformation. However, the PXCM does not recover its shape unless tensile stress is applied. On the other hand, bimetal, composed of two metals with different thermal expansion coefficients, generates internal stress due to thermal strain and bends with temperature change [3]. If bimetals are incorporated into a part of the PXCM, it is expected that the PXCM will not only deform under compressive and tensile loads but also change its shape by heating and cooling. The purpose of this study is to fabricate a Thermally Induced PXCM (TIPXCM), which recovers its shape by temperature change after compressive deformation and exhibits pseudo shape memory property by using bimetals in the curved beams of PXCM. The optimum shape of the TIPXCM was designed by analyzing the deformation behavior under compressive loading and heating using the finite element method (FEM). Experiments were conducted using the fabricated TIPXCM, and the deformation associated with temperature change was measured using a high-speed camera and image analysis software to evaluate the relationship between temperature and strain.

As a result of the simulation, plastic deformation due to stress concentration was predicted to occur at both ends of the beam. To solve this problem of stress concentration, we designed a lattice structure consisting of bimetal beams whose ends were simply supported. The relationship between temperature and strain was measured by heating and cooling experiments on a half-unit cell of TIPXCM. The half-unit cell rapidly contracted at around -135°C and rapidly expanded at around 167°C owing to the snapping of the bimetallic beams, which are characteristic of this metamaterial. Then, we constructed TIPXCMs by arranging the unit cells. When the TIPXCM was heated, snap-through occurred in a step-by-step manner. The first snap-through triggered a chain reaction of deformation in other parts, and finally, the TIPXCM recovered more than 20% of its strain. This is more than twice as large as the strain recovery of Ti-Ni shape memory alloys (7-8%). This is a unique property of TIPXCM.

Keywords: *Discrete Element Method, Cyber-Physical System, Digital Twin*

Nowadays, the development of a digital twin has received more attention in industries. This trend is no exception in powder industries. Towards the realization of a digital twin for a powder process, advanced modeling and simulation have been tackled. Therein, the discrete element method (DEM) [1] will be extensively employed. In my group, several key technologies for the DEM have been developed to construct the digital twin. The Signed Distance Function (SDF) [2] is useful to create the arbitrary shape wall boundary, even when the DEM is applied to the solid-fluid mixture systems [3,4]. The coarse-grained DEM [5] makes it feasible to simulate industrial powder systems efficiently. The geometrical approximation-based capillary force model [6] is shown to be effective to simulate industrial wet-particle systems. These technologies are integrated as an in-house code referred to as FELMI [7-9]. In this presentation, I will talk about the recent progress of the FELMI code and its application for the digital twin.

Key Words: *Discrete element method, Pot blender, Mixing mechanism, Velocity gradient*

Powder mixing is widely employed in mineral, ceramic, nuclear and pharmaceutical engineering. To achieve an efficient mixing process, various type of mixers has been developed. A pot blender with both blending and storage capabilities offers an advantage over a conventional rotating drum. Unlike a typical rotating drum, the pot blender can simultaneously rotate and swing in controlled amplitude and frequency. Since the powder mixing in the pot blender is significantly influenced by the operating conditions and physical properties of the raw powder, the mixing operation of the pot blender has not been established so far. Therefore, in this study, we aim to elucidate the mixing mechanism of the pot blender using the discrete element method (DEM) [1] with a wall boundary model based on the signed distance function [2], which has been validated in the pot blender system [3]. Simulation results show that the mixing mechanism of the pot blender is mainly convective mixing in the rotational direction and shear mixing in the axial direction. Besides, as shear mixing in the axial direction become stronger due to the swing of the pot, diffusive mixing is suggested to intensify because the granular temperature increases with the variance of the axial particle velocity. A systematic series of simulations reveal that the velocity gradient in the axial direction, which mainly determines the axial mixing performance, is unaffected by particle density. Namely, the particle density has an insignificant influence on the mixing mechanism in the pot blender. Considering the relationship between the variance of axial particle velocity and granular temperature, the particle filling ratio is shown to significantly influence the mixing efficiency in the pot blender. Besides, dependency of the shear and diffusive mixing on Lacey's mixing index in the pot blender is newly clarified [4]. Consequently, the present study demonstrates novel insights into the mixing mechanism of the pot blender and comprehensive findings on the effects of particle density and particle filling ratio on the mixing process in the pot blender.

Key Words: *DEM-CFD, Tote Blender, Particle mixing, Air effects*

Homogeneous mixture of powders is in great demand for industrial products and produced through different kinds of mechanical mixers. Tote blender [1], widely used in pharmaceutical industry, has received scant attention in academic field. On the one hand, the features of flow regimes inside it have not been clearly studied. In addition, it's noted that air drag force acting on relatively small particles is not negligible during particle mixing [2], which is however not examined in tote blender hitherto.

By our in-house DEM-CFD method named FELMI [3], a reliable tool to simulate gas-solid flow, this study investigated the effects of air on particle mixing in a tote blender for the first time. To obtain comprehensive understanding, different rotation speeds (flow regimes), filling levels and particle sizes were involved. By visualization of flow regimes and evaluation of mixing state, the underlying air effects were analysed in detail. It's found that the mixing performance of small particles was significantly improved compared with that of larger ones in terms of Lacey's mixing index, since the air drag force changed the flow behaviour of small particles. More importantly, this pattern was observed in all the operating conditions, proved to be a universal rule.

This work provides novel insights about the prominent functions of air on mixing in the tote blender. It also conveys an import concept that air effects cannot be ignored when particles are small, which should be carefully considered in all the tumbling blenders.

Key Words: *DEM, Blast Furnace Bell-less Top, Burden Distribution*

Blast furnace is a large chemical reactor that is predominantly used for ironmaking purpose. Burden distribution plays an important role in achieving stable and efficient operation in a modern ironmaking blast furnace. Charging materials, e.g. coke and pellets, flow from upper hopper through a rotating chute and are distributed on the burden surface. The surface profile formed affects the gas flow distribution and particle descent behavior inside the blast furnace shaft. In present work, the authors proposed a DEM based numerical model to predict the burden distribution in a blast furnace and studied various aspects of burden distribution, including: falling trajectory of material, development of the burden profile at the throat, coke collapse, size segregation, and the gas velocity distribution across the furnace radius. Furthermore, the authors had tried to utilizing the burden distribution, thus gives a continuous production from the furnace as well as increase in the gas contact efficiency and a decrease in the energy consumption.

Key Words: *Granular flow, segregation, rotating drum, ellipsoids*

Rotating drums are widely used in industry for mixing, milling, coating and drying processes. Particle mixtures with different physical properties in the rotating drums could segregate in the both radial and axial directions from an initially well-mixed state. In this presentation, we report the segregation phenomenon induced by particle shape. Particle shape used in our work is spheroidal which can be described by the parameter of aspect ratio (AR) defined as the ratio of both principal diameters of spheroids. Aspect ratio varies within a large range representing from oblate (AR<1) and spherical (AR=1) and problate shapes. Binary mixtures of spheres and spheroids are used in the discrete element method (DEM) simulation, and the segregations in both radial and axial directions are investigated. The results show that in a short drum, particle shape difference can cause radial segregation, but the segregation patters such as the locations of spheres and spheroids vary with the magnitude of the shape difference. With particle shape difference increasing, the segregation patterns could totally be reversed which can be explained by the reduced diffusion mechanism. For a long drum, the results show that for spheroid-sphere mixtures, spheres tend to segregate axially to the middle section of the drum, particularly for spheroids at aspect ratios = 0.67 and 2.0. The analysis reveals that the frictional end walls and the segregation developed in the radial direction induce the axial flow of particles, and are essential for the development of axial segregation.

Systematic Phase-field Lattice Boltzmann Simulations to Investigate the Coherency Point in Semi-solid Deformation

Namito Yamanaka[1*], Shinji Sakane[1] and Tomohiro Takaki[1]

[1] Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto, 606-8585 Japan;
m0623033@edu.kit.ac.jp, sakane@kit.ac.jp, takaki@kit.ac.jp

Key Words: *Semi-solid Deformation, Solidification, Phase-field Method, Lattice Boltzmann Method, GPU computing*

Semi-solid deformation occurs during casting with external forces of alloys. When the solid fraction exceeds a coherency point where grains impinge and a continuous network of grains becomes coherent, the semi-solid material exhibits a rheological behavior, which causes Reynolds dilatancy, such as in soil [1]. As the Reynolds dilatancy in semi-solid deformations causes serious solidification defects such as band segregation, pores, or cracks, identifying the coherency point based on various solidification conditions is critical.

Previous studies [2, 3] have reported that the crystal morphology, solid fraction, and deformation rate in semi-solid deformations are dominant for the coherency point. However, systematic investigations of these various factors have yet to be performed. To enable these investigations, numerical studies are indispensable. Still, no numerical models exist that can accurately express a multi-physics problem in semi-solid deformations, including solid–liquid transformation, fluid flow, and the motions and collisions of solids. In our previous study, a polycrystalline solidification model coupled with a multi-phase-field method, lattice Boltzmann method, and equations of motions of solids (which we termed a multi-phase-field lattice Boltzmann model) was successfully applied to a case of semi-solid deformation [4].

In this study, the multi-phase-field lattice Boltzmann method [4] was used to conduct systematic simulations of semi-solid deformation of an Al-Cu alloy under various conditions by changing the crystal morphology, solid fraction, and deformation rate. We investigated the effects of these factors on the coherency point through these simulations. The simulations for semi-solid deformation were accelerated by parallel computing using multiple graphics processing units.

Key Words: *Microstructure, transport, mechanical properties, batteries, structure-property relationships*

Atomic scale calculations at the classical and quantum scale are used to probe how chemo-mechanical phenomena impact the performance of solid state batteries. Microstructure and mechanical properties of the solid electrolyte, metal anode, and the interfaces between them are considered. Phenomena that are investigated include the elastic properties of the bulk materials, local softening of elastic properties in the vicinity of grain boundaries, ideal strength, transport along grain boundaries, and interfacial adhesion. These properties are connected to failure modes associated with battery operation, such as void formation and dendrite nucleation at the electrode/electrolyte interface. These analyses reveal design guidelines for microstructural properties that enable robust battery operation.

Catalytic Performance Affected by Hydrogen Spillover Mechanism: A DFT Study

Hsin-Yi Tiffany Chen[1*] and Kai-Yu Tseng[1]

[1] Department of Engineering and System Science, National Tsing Hua University
No. 101, Section 2, Kuang-Fu Road, Hsinchu, Taiwan 300044
hsinyi.chen@mx.nthu.edu.tw

Key Words: *Ru/MgO, catalyst, hydrogen spillover, metal-support interaction, DFT*

Density Functional Theory (DFT) based electronic structure calculations have been used widely in modern Materials Science, Chemistry and Physics to disclose profound mechanisms of interest. Catalysts play a critical role in these energy conversion and storage technologies via enhancement of reacting rate, efficiency, selectivity of the relative chemical transformations. DFT can assist in understanding their mechanisms, improving material designs and predicting their performance. Here, I will focus on the correlation understanding between the hydrogen spillover mechanism and some catalytic reactions such as ammonia synthesis for future energy carrier application. First, we analyze the molecular or dissociative adsorption of on a single Ru atom as a benchmark or reference. Secondly, we analyze the binding energies between Ru-MgO(111) to understand their metal-support interactions. Thirdly, we would like to understand the physisorption and chemisorption of H_2 on MgO(111) supported Ru catalysts. Fourthly, we gradually adsorb more and more hydrogen atoms on Ru/MgO catalyst and attempt to understand the condition of triggering the occurrence of the phenomena of hydrogen spillover. The role of the supported metal particle is essential as it favours the spontaneous dissociation of H_2, a process that could rarely occur on the bare oxide surface without surface modification. However, MgO(111) seems to be capable of dissociating H_2 molecule. In this system, hydrogen spillover is not necessary to occurs at high hydrogen saturation conditions. Finally, we aim at correlating metal-support interaction with hydrogen spillover to quickly predict the catalytic performance and catalyst designs to reduce hydrogen poison problems or increase more active sites.

Key Words: *Rechargeable batteries, manufacturing process, digital twin, multiscale modelling, machine learning*

Lithium ion batteries (LIBs) are a very important technology for our societies. Their performance is strongly influenced by the mesostructure of their porous electrodes. This mesostructure results from a complex process encompassing multiple steps and numerous parameters. Its understanding and accelerated optimization is vital for the future of battery technology.
In this lecture I discuss a digital twin for accelerated optimization of the manufacturing process of LIBs we are developing within the context of the ARTISTIC project.[1,2] Such digital twin is supported on a hybrid approach encompassing a physics-based multiscale modeling workflow, machine learning models and high throughput experimental characterizations. Different steps along the battery cells manufacturing process are simulated, such as the electrode slurry, coating, drying, calendering and electrolyte infiltration. The multiscale physical modeling workflow couples experimentally-validated Coarse Grained Molecular Dynamics, Discrete Element Method and Lattice Boltzmann simulations and it allows predicting the impact of the process parameters on the final electrode mesostructure in three dimensions. The predicted electrode mesostructures are injected in a continuum performance simulator capturing the influence of the pore networks and spatial location of carbon-binder within the electrodes on the solid electrolyte interphase formation (for anodes) and the electrochemical response (of anodes vs. lithium, cathodes vs. lithium and the full cells). Machine learning models are used to accelerate the physical models' parameterization, to mimic their working principles and to unravel manufacturing parameters interdependencies from the physical models' predictions and experimental data, and as a guideline for reverse engineering. The predictive capabilities of this digital twin, coupling physical models with machine learning models, are illustrated with results for different electrode formulations. Finally, the free online battery manufacturing simulation services offered by the project[3] and our virtual reality technology supported on the project results to optimize battery electrodes and for the project results dissemination are illustrated through several examples.

Energetics and Dynamics of Lithium Intercalation in Graphite from Machine Learning-based Energy Model

Po-Yu Yang[1] and Chun-Wei Pao[1,*]

[1] Research Center for Applied Sciences, Academia Sinica, 128 Sec. 2 Academia Rd., Taipei 11529, Taiwan

Email: cwpao@gate.sinica.edu.tw

Key Words: *Atomistic Simulation, Machine Learning, Lithium Intercalation, Graphite*

Graphite has been widely used as the anode material of commercial lithium ion batteries for almost three decades. Recent studies have indicated that the capacitance of Li-graphite anodes could reach beyond the theoretical magnitude of 372 mAh/g, suggesting that there still lacks comprehensive, atomistic insights into the detailed intercalation energetics and dynamics of lithium intercalation into graphite. Herein, a hybrid machine learning (ML) energy model combining the spectral neighbor analysis potential (SNAP) and the dihedral-angle-corrected registry-dependent (DRIP) model were trained for Li-graphite system. A number of high lithium intercalation density configurations, including LiC_2 and multi lithium layer intercalation in conjunction with different graphite stacking types were taken into account in the training set, allowing us to explore the true upper limit of lithium intercalation into graphite. The trained hybrid ML energy model allows us to perform extensive large-scale atomistic Monte Carlo sampling of lithium intercalation into graphite, while retaining high fidelity in potential energies and atomic forces prediction with respective density functional theory (DFT) calculations. Our simulation results suggest that during thermodynamic equilibrium condition, it is highly likely that the actual capacity of Li-graphite anode is much higher than that of LiC_6; however, it is very difficult to attain due to the constrain imposed by lithium diffusion kinetics.

Modeling and Simulations of the Structure and Lithiation Mechanism of Silicon Oxycarbide Ceramics

Li-Hung Chueh and Chin-Lung Kuo

Department of Materials Science and Engineering, National Taiwan University

Key Words: Li-ion Batter, Silion Oxycarbide Ceramics Glass, First-Principles Calculations, ReaxFF Modelling

Silicon oxycarbide (SiOC), a polymer-derived ceramic, is considered as a promising anode material for the next generation lithium ion batteries primarily owing to its excellent electrochemical and cycling performance during the lithiation and de-lithiation processes. However, the structure characteristics and the lithiation mechanism of silicon oxycarbide remain very controversial and unclear yet to date. In this study, we employed *ab initio* molecular dynamics simulations to generate the structure models of amorphous silicon oxycarbide within various chemical compositions ($SiC_{3.3}O_{1.6}$, $SiC_{2.2}O_{1.6}$, $SiC_{1.65}O_{1.6}$, $SiC_{0.8}O_{1.6}$, $SiC_{1.65}O_{1.1}$, $SiC_{1.65}O_{0.6}$) and then investigate the atomistic mechanisms of the Li-ion intercalation as well as the origin of the huge capacity loss upon the 1st cycle of lithiation. Our results first revealed that the C atoms are very likely to segregate out and form the graphitic-like free C phase within the remaining SiOC glass in the amorphous material bond network. As the C/O ratio is low, the free carbon atoms may simply form fragmented amorphous graphene layers in the composite material bond network, while they can turn into the multi-layer disordered graphene phase as the C/O ratio is much further increased. Based on those SiOC structure models generated, their lithiation mechanisms were found to exhibit a very interesting and distinct intercalation behavior from other anode materials considered. During the early stage of lithiation, the intercalated Li ions were mainly located at the interfaces between the SiOC glass and the free C phase. Our charge density analysis further showed that the electrons were mainly accommodated by the free C phase while the Li ions were predominantly adsorbed on the O atoms of the SiOC glass. During the 2nd stage of lithiation, the Li ions started to migrate into the SiOC glass region and sequentially break the Si-O bond networks. Upon the end of lithiation, the Li storage capacity of the silicon oxycarbide anode was found to be within the range between 800 and 1200 mAh/g, in good agreement with the recent experiments. Our simulation results further revealed that the Li storage capacity and the irreversible capacity loss in the 1st cycle of lithiation are largely determined by the C content in the silicon oxycarbide anode. A detailed explanation of the underlying physics and the associated atomistic lithiation mechanisms of the silicon oxycarbide anode will be addressed in this presentation.

Theoretical Insights Toward Alleviating Lattice-Oxygen Evolution in Li-rich Layered Manganese Oxide Cathode Materials

Kuan-Yu Lin, Santhanamoorthi Nachimuthu, Han-Wen Huang, and Jyh-Chiang Jiang* *
Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan, e-mail@jcjiang.ntust.edu.tw

Key Words: *$LI_{1.2}NI_{0.2}MN_{0.6}O_2$, OXYGEN EVOLUTION, AIMD*

Recently, Li-rich layered manganese oxide-based cathodes have drawn much attention for the next-generation lithium-ion batteries due to the large discharge capacities and low cost. However, the lattice oxygen release and subsequent surface densification during cycling inevitably lead to their instability, which incurs capacity failure at high voltage. Improving the stability of lithium-rich cathode materials is important in refining the overall performance of lithium-ion batteries. In my presentation, I will show the mechanism of lattice oxygen evolution and related electronic properties of $Li_{1.2}Ni_{0.2}Mn_{0.6}O_2$ (LNMO) cathode materials.[1,2] Then I will illustrate the lattice oxygen release in LNMO cathode surface can successfully suppress through the doping using density functional theory (DFT) calculations and ab initio molecular dynamics (AIMD) simulations.

Key Words: discrete element method, non-Bagnold flow transition, force network community, force chain duration time

A granular flow is the collective motion of discrete solid particles and its continuum modeling has challenged researchers for decades due to its multiphasic flow characteristics, especially at the solid-liquid phase transition. This is because the interaction mechanisms among the constituent particles may have changed from repulsive binary collisions to enduring frictional contacts with multiple neighbors, leading to the formation of force chain structure. This chain-like structure forms an internal network to transmit momentum more effectively than collision-induced transport and hence is worth investigating how the flow behavior changes accordingly. On the framework of discrete element simulation, we implemented two algorithms to extract the force chain structure in a steady granular flow. The first approach uses the depth-first search to identify force chains in a plane shear flow. Statistical data of the length and the lifetime of the longest chain shows monotonic decrease with the flow inertial number, I. A lower I indicates a more solid-like flow state and the finding confirms the speculation that the force chains also develop to a wider spatial extent. The second approach implements the Louvain greedy algorithm to identify force chains as network communities and the number of force chain disks is evaluated across the depth of surface granular flows of different heights and inclinations. The statistics shows that more disks are engaged to develop force chains in deeper layer and such depth-variation is only noticeable when the flow is more solid-like with a sufficiently low Froude number. With decreasing Froude number, the force chains carry a growing portion of the flow internal stress but an upper limit around 0.6-0.7 is consistently detected. The most intriguing finding reveals that the sudden rise of force chain disk number and their carried stress portion is linked to a degradation of flow velocity profile from the Bagnold profile, known to exist when collision is the primary interaction mechanism.

Simulations of Granular Flow Behaviors and Mixing Process in Fluidized Bed Mixer

Shih-Hao Chou[1*], Shu-San Hsiau[1]

[1] National Central University, No. 300, Zhongda Rd., Zhongli District, Taoyuan City, Taiwan (R.O.C.), charry0299@gmail.com

Key Words: *Fluidized Bed, Additive Manufacturing, Granular, Mixing, Two-phase Model*

As per ASTM, additive manufacturing (AM) is defined as the process of joining materials to fabricate objects from 3D-model data (typically layer upon layer), as opposed to subtractive-manufacturing methodologies [1]. Although AM has been used as a material-processing method for more than 20 years, it has only recently been considered an important commercial manufacturing technology. The AM process can involve var- ious materials such as metals, ceramics, or composites. However, metal products are most widely used in industrial applications.

A significant portion of the operating costs of commercial AM equip- ment is due to the metal powders used in the AM process. The fine metal powder that is used for laser melting is expensive, and thus it is important to avoid any wastage. In most cases, only a small portion of the powder that is placed on the bed is actually soldered into a component. Most of the powder is not melted, and is thus available for re-use. However, the recycling powder have to be mixed with the fresh powder in the final step before it can used to the next process. The segregation phenomena is a common problem in the mixing process or transportation process. Therefore, it is importantly to understand the theory and the mechanism of powder segregation/mixing, and to reduce the probability of occurrence. Powders can be mixed by mechanical excitation, gas-flow agitation, gravity-driven free-falling, and many other different complex methods [2]. The mechanisms of powder mixing include convective mixing, shear mixing and diffusive mixing [3-5].

In this study, we performed numerical simulation to investigate gas-solid interaction problems in a fluidized bed powder mixing system, in which a coupled CFD-DEM method was used to investigate the mechanism of gas flow and the particle tracking for granular flow. In the DEM, Lagrangian particle tracking method was employed to calculate the particle motion. CFD analysis by using Eulerian model was used for the determination of velocity and pressure field for the gas phase. we analyzed the velocity and pressure changes of the fluid field. Next, we also investigate the trajectory, velocity and granular temperature of the granular powder, and analyzed the mixing intensity with time revolution and mixing rate by using the mixing index. It showed that both the gas velocity and the inclined angle of air inlet affect the mixing rate and mixing degree.

How to enhance the discharge flow rate of granular particles moving through a hopper under the influence of gravity is an important engineering and industrial question. Surprisingly, an optimally placed obstacle in a hopper allows particles to exit the hopper more efficiently, similar to how proper placement of traffic signals and signs can improve traffic jam. An obstacle placed too far from the hopper exit allows so many particles to pass that they are prone to congest as they are funneled together. An obstacle placed too close lowers the chance of congestion at the exit but allows so few particles to pass that it reduces overall flow. An optimally placed obstacle creates a flow rate enhancement by channeling the maximum number of particles that can smoothly merge. Using a novel modeling technique that simplifies the complications of interparticle forces, we show that this phenomenon can also be created by either artificially guiding the particles into the free space under the obstacle or by narrowing the hopper exit angle below the obstacle. These findings can be used in the design of hoppers that discharge granular particles more efficiently and we expect them to have broad industrial applications.

Even nowadays it is still a challenge to predict numerically the failure behavior of concrete under compression. Multiscale models have been used to better understand the influence of the distinct phases of the concrete on the fracture process. In this sense, this work proposes an extension of the mesh fragmentation technique developed by Manzoli et al. [1] to account for the complex failure behavior of concrete under compression. The concrete is represented using a mesoscale approach, as proposed by Rodrigues et al. [2], however, the pairs of interface elements inserted into the standard finite element mesh to define the potential fracture paths are duplicated to describe the compressive failure as a combination of tensile and tangential constitutive models.
The use of these two damage models makes it possible to represent the debonding (opening) between the aggregates and matrix due to local tensile stress concentration, i.e. the fracture propagation in mode I, as well as the sliding process that corresponding to the fracture propagation in mode II. Furthermore, adopting adequate parameters, these models even allow representing the friction condition between the concrete specimen and the steel loading plates. Numerical examples assuming different specimen slenderness as well as the different friction restraints between loading platen and concrete specimen are carried out. The numerical results are compared qualitatively and quantitatively against the experimental results found in the literature [3], demonstrating the proposed approach is promising to describe the failure process of concrete in compression.

Key Words: Strain-gradient plasticity, dissipative theory, duality, finite element method, upper and lower bounds

Strain-gradient plasticity refers to a class of extensions of classical elastoplasticity in which size-dependent effects are accommodated through the introduction of a length scale together with gradients of plastic strain. The area has received sustained interest, with multiple theoretical, experimental and computational contributions (see for example [1] and the references therein).

Strain-gradient theories are generally energetic or dissipative in nature. The former refers to models in which the plastic strain gradients are incorporated in a defect energy, while in the latter model the plastic strain rates and their gradients are determined through an extension of the classical associative flow relation and a yield function that depends on microstresses, which are not known in the elastic region.

This presentation focuses on the dissipative version of rate-independent strain-gradient plasticity, for which yield and plastic flow must be considered at the global level. This is a generally intractable problem, and so it is useful to develop methods for approximating yield. One such approach is discussed here: it draws on the methods of limit analysis together with primal and dual versions of the global problems, to establish conditions for lower and upper bounds to the elastic threshold. The approach is illustrated through various examples, using a computational approach with penalization.

Key Words: Coupling finite elements, Vuggy porous media, Non-matching meshes

Studying the characteristics of rock formations is of great importance in a number of engineering applications, such as geothermal energy extraction, nuclear waste storage, CO_2 sequestration, and oil and gas extraction [1]. In terms of hydraulic analyses, the presence of geological features such as fractures, vugs and barriers can significantly affect the equivalent permeability of the porous medium [2], but modeling vuggy fractured porous media is still a challenging problem, since the geometry of fractures and vugs are very complex and involves several dimensions and arrangements. In this context and based on the finite element method, conventional meshes require a significant computational effort when dealing with problems with multiple scales, since many transition elements are required to smooth the transition between the dimensions. This work proposes to model each geological structure completely independent from each other (i.e., in a non-matching way) and couple them in the porous medium mesh by means of coupling finite elements (CFE). The CFE can be inserted during the pre-process stage and does not add new degrees of freedom to the system of equations [3]. The technique was applied in 2D single-phase flow problems in vuggy fractured porous media, with incompressible fluid. To verify and validate this technique, the results were compared against the ones obtained with conform meshes, which were used as reference. Based on this comparison, a good similarity was observed between the responses, as well as a significant reduction in the number of elements used to discretize the problem. The effects caused by fractures that act as barriers (fracture less permeable than the porous media) were also captured.

Key Words: Temporal multiscale, Plasticity, Dislocation Dynamics

This talk aims to understand and exploit the slow time-scale behavior of rapidly evolving microscopic dynamics. The microscopic systems considered are posed in terms of systems of non-linear ordinary differential equations, not necessarily containing an a priori split into fast and slow variables. Such a question arises naturally and ubiquitously in efforts to understand macroscopic dynamics, on engineering time-scales, of well-accepted models of microscopic dynamics that, however, are not amenable to practical computing over the much, much larger macroscopic time-scales of interest. This is because there is a vast separation of time scales involved between the dynamics of the macroscopic variables of interest and the microscopic dynamics, and evolving the microscopic dynamics directly fails to address the question of the macroscopic dynamics.

The methodology employed involves a computational scheme based on fundamental mathematical theory that a) defines appropriate `coarse' variables corresponding to the microscopic dynamics that evolve in a stable manner on the coarse time scale; b) determines the equation of evolution for such variables; and c) defines a practically useful strategy for accurately initializing short bursts of microscopic runs for the evolution of the slow variables, without special requirements on the nature of the microscopic dynamics.

We will illustrate the theory with examples that violate ergodicity and include both conservative and dissipative behavior. The coarse graining of discrete dislocation dynamics to a pde-based plasticity model without relying on constitutive assumptions will also be demonstrated.

Key Words: *Polymer nanocomposite, Interphase, Multiscale modeling, Plastic deformation*

In this study, we proposed the multiscale bridging approach to describe the elasto-plastic behavior of polymer nanocomposites by combining the molecular dynamics (MD) and finite element (FE) homogenization method. It has been reported that the precise characterization of interphase elasto-plastic constitutive law is critical in the prediction of the fracture toughness and fatigue crack growth behavior [1] as well as the strength of polymer nanocomposites. Yang et al. [2] developed the multiscale bridging approach to elasto-plastic behavior of polymer nanocomposites including the carbon nanotubes by combining the molecular dynamics (MD) and micromechanics theory. However, the multiscale bridging method based on the MD and FE homogenization method has not been developed. Because the FE homogenization method is more accurate than the analytic micromechanics solutions, it is critical to develop the multiscale bridging method based on the MD and FE homogenization method to describe the elasto-plastic behavior of polymer nanocomposites. We have used a three-phase continuum homogenization model, which include the interphase zone as well as the matrix and particle. The interphase elasto-plastic properties are inversely obtained by the MD and FE homogenization method. For various nanoparticulate size, the interphase properties obtained from the proposed method are compared with those of the multiscale bridging method based on the MD and analytical mean-field homogenization (MF) method. Furthermore, for the efficient characterization of the interphase elasto-plastic constitutive law, the proper orthogonal decomposition (POD) is applied.

Key Words: *Epoxy, Hygroelastic aging, Molecular dynamics, Diffusion*

This study demonstrates moisture uptake and hygroelastic degradation of epoxy-based nanocomposite using classical molecular dynamics simulation and Monte Carlo simulation. The hygroelastic aging is one of the representative aging caused by continuous exposure to humid environment. Water molecules absorbed inside epoxy and epoxy-reinforcement interface act as a plastisizer to decrease elastic modulus of cross-linked network. Moreover, anchored moisture occupying the free volume in epoxy result in swelling and eigenstress. Therefore, we performed a systematic combinatory simulation of moisture transport and resultant hygroelastic aging of epoxy-based nanocomposite. Considering the humidity of epoxy's service condition moisture uptake was studied by using a Monte Carlo simulation. From the moisture content-volumetric expansion relation, the swelling coefficient of nanocomposite was determined. According to the moisture content, the elastic modulus of nanocomposite was determined from uni-axial tension test. To study the degradation of epoxy-nanocarbon interface by the moisture invasion, simple laminated unit cell model was constructed. From mode1 and mode2 decohesion test, normal and tangential cohesive law was determined according to the hygroelastic aging. Finally a multi-scale hygroelastic constitutive model was proposed and sequentially bridged to the MD simulation results.

Computational modeling to evaluate effect of the partial debonding on fracture toughness of polymer nanocomposite

Wonseok Lee[1*], Kyungmin Baek[1] and Maenghyo Cho[1]

[1] Department of Mechanical Engineering, Seoul National University, Seoul, South Korea,
leews91@snu.ac.kr, myminvva@snu.ac.kr, mhcho@snu.ac.kr

Key Words: *Fracture toughness, Polymer nanocomposite, interfacial debonding, Matrix plastic yielding, Finite element analysis*

Due to significantly improved properties and multifunctional behaviors by nanoparticles, intensive researches on nanocomposites have been performed. One of the most interesting features is the fracture toughness enhancement of the nanocomposite even at low filler concentrations. Many researchers [1,2] have developed theoretical models to predict the toughness enhancement of nanocomposites, considering the main toughening mechanisms such as the interfacial debonding, the plastic yielding of nanovoids and localized shear banding of the polymer. Zappalorto M et al. [2] proposed multiscale model base on the assumption that the interface between the polymer matrix and the particles is uniform. However, in the process of synthesizing the nanocomposite, It is impossible to generate unifom interface between the components, and voids could be generated without interfacial bonding force.

In this study, a computational modelling based on finite element (FE) analysis is proposed for analyzing the fracture toughness of silicon carbide (SiC)/epoxy nanocomposite. We intensively address energy dissipated by two mechanisms for toughness enhancement: interfacial debonding and the plastic yielding of nanovoids. A three phases nanoscale system (particle-interface-matrix) is modelled, and the analytical model proposed by Zappalorto M et al. [2] is applied to calculate the parameters for FE analysis such as critical debonding stress and extension of the plastic zone. Crack-induced stress at the macroscale is transferred into the nanoscale FE model through the scale-bridging method. The simulation results show that the dissipated energy of the plastic yielding of nanovoid increase nonlinearly as the specific debonding area increase, which proves that the interfacial partial debonding have a significant effect on the toughness enhancement of the nanocomposite. The proposed FE modeling approach is expected not only to overcome the limitations of the analytical model that cannot depict partial debonding, but also serve as a foundation for designing nanocomposites.

Artificial neural networks (ANNs) are being applied in many research fields. Among them, the neural network constitutive modeling studies on nonlinear problems in the field of mechanical engineering are important. In this study, three different types of neural models: multi-layer perceptron neural network (MLPNN), generalized regression neural network (GRNN), radial basis function neural network (RBFNN) are used to construct neural network constitutive models (NNCMs) for hyperelastic materials. We focus on the two cases of ANN training of data set: (i) the conventional hyperelastic models such as the Mooney-Rivlin model, and (ii) full atomistic molecular dynamics (MD) simulation results. Here, we obtain the optimal hyperparameters empirically at each neural network modeling to construct optimal NNCM. These three models were compared based on statistical error analysis. The results indicated that RBFNN model is the most accuracy through RMSE, MAE, and R values. We apply the proposed NNCM model to the data-driven computational mechanics (DDCM) to verify the proposed NNCM model. Additionally, the data-driven two-scale finite element analysis framework is proposed by using the microscopic equilibrium equation solution data-driven ANN model with proper orthogonal decomposition method. As results, the data-driven solver shows the superiority of the performance of RBFNN model than the other neural network models.

Effect of Heterogeneous Curing Temperature on Crosslinking Morphology and Mechanical Properties of Epoxy Thermoset Plastic: A Coarse-Grained Molecular Dynamics Simulation

Jiyong Ahn[1*], Hyungbum Park[2] and Maenghyo Cho[1]

Key Words: *Coarse Grained Molecular Dynamics, Epoxy, Heterogeneous Curing Temperature, Mechanical Properties*

Because epoxy has excellent thermomechanical properties, it is used in various industries such as electronic, aircraft, automotive and composite materials. The excellent physical properties of the epoxy are due to the cross-linking network formed by chemical bonding between the epoxy resin and the crosslinking agent. Various studies using molecular dynamics have shown that factors such as crosslink density, crosslinking process, curing agent structure, and ratio affect crosslinking network formation [1-3]. According to a recent experimental report, the heterogeneous temperature during the crosslinking process forms a heterogeneous crosslinked network, which greatly affects the mechanical properties of the epoxy [4-6]. However, it is difficult to analyze the crosslinked network in detail with an experimental approach, and the analytical approach using simulation is also insufficient due to the limitation of the scale.

In this study, a computational model based on molecular dynamics is proposed for analyzing the effect of the heterogeneous curing temperature on crosslinked network and mechanical properties. We extended the length scale of the classical molecular dynamics model using Coarse Grained Molecular Dynamics (CGMD). And 10 cases of heterogeneous heating simulation were performed. The simulation results showed that the more heterogeneous the curing temperature is, the more heterogeneous the crosslinked network becomes. In the heterogeneous crosslinked network, area with a low crosslinking density was observed. This area was vulnerable to void formation, resulting in an early local yield, which consequently accelerated the yield of the material. The proposed CGMD modeling approach is expected not only to overcome the limitations of the classical molecular dynamics model that cannot depict heterogeneous curing, but also serve as a foundation for designing nanocomposites using epoxy thermoset plastic.

Key Words: *Coarse-grained molecular dynamics, polymer nanocomposite, nanoparticle agglomeration, particle swarm optimization, artificial neural network*

As polymer nanocomposites have attracted significant attention over the years for enhanced thermomechanical, electrical properties and multifunctional behavior, many attempts have been made to analyze characteristics of polymer nanocomposites at molecular level using the molecular dynamics (MD) simulations [1, 2]. However, due to limitations of time and length scale resulting from atomistic-level calculations, the interaction between multiple nanoparticles could not be taken into account, and therefore the correlation between nanoparticle distribution and mechanical behavior of nanocomposites is still not fully understood.

In this study, we present multiscale simulation framework based on the coarse-grained MD simulations to investigate mechanical behavior of silicon carbide (SiC) / polypropylene (PP) nanocomposites. We adopted coarse-grained MD simulations as an effective tool for the advantage of maintaining the molecular details while extending time and length scale of simulation with less computational efforts. The new coarse-grained potential, composed of bonded and non-bonded terms, is derived through optimization process based on artificial neural network (ANN) assisted multi-objective particle swarm optimization (MOPSO) to fit certain key thermomechanical properties of SiC/PP nanocomposites obtained from full atomistic MD simulations. The predictions of coarse-grained model single nanoparticle and two nanoparticles are in very good agreement with reference data. Based on that result, we conduct uniaxial tensile deformations by varing polymer-nanoparticle and nanoparticle-nanoparticle interactions to deepen the understanding of microscopic mechanism of nanoparitcle distribution on stress-strain behavior The proposed multiscale simulation approach can elucidate effect of agglomeration of multiple nanoparticles on nanocomposites, and it can provide insight on efficiently designing the nanoparticle/polymer nanocomposites.

Key Words: *Molecular Dynamics, h-BN sheet, Nanocomposites, Dielectric constant, piezoelectric constant*

In this study, Molecular dynamics simulation(MD) is used to investigate the Electroelastic properties of hexagonal crystallographically boron nitride nanosheets (h-BN nanosheets). Randomly generated Stone-Wales(SW) defect in h-BN nanosheets is considered in the simulation to reveal how the defect in h-BN affects the electroelastic properties. Based on the linear piezoelectric constitutive law, both reverse piezoelectric and direct piezoelectric simulation were implemented. In order to describe electroelastic behaviour of h-BN, several Tersoff potential models were applied. In reverse piezoelectric simulation, varying electric field was applied along the in-plane direction of h-BN and the resultant polarization and induced stress were used to determine the dielectric constant and the piezoelectric constant, respectively. In direct piezoelectric simulation, h-BN was mechanically elongated without electric field. From the strain-polarization and strain-stress relation, piezoelectric constant and young's modulus of h-BN were determined. As the SW defect increases, the dielectric constant increases as a result of relative electric displacement of boron and nitrogen atoms. On the other hand, the piezoelectric constant showed increasing as well as decreasing trend depending on the Tersoff potential model applied to the simulation. The Young's modulus was found to decrease as the number of SW defect increase regardless of the Tersoff potential model.

Key Words: *Laminated Composites, Thermo-Mechanical-Viscoelastic Analysis, Mixed Variational Theorem, Laplace Transformation*

Recently, composite materials have been widely used in various engineering applications due to their high stiffness-to-weight ratio and multifunctional characteristics. Although the laminated composite plates has a great structural performance, mechanical imperfections such as layer delamination can be induced by transverse shear and normal stresses. There are many theories developed to accurately predict these transverse stresses, such as the well-known conventional theories (FSDT; first-order shear deformation theory) and many other refined shear deformation theories (HSDT; higher-order shear deformation theory, EHOPT; efficient higher order plate theory, EFSDT; enhanced first-order shear deformation theory).

When the composite materials are used in severe operating conditions such as extremely high temperature environments, composite structures have thermal expansion as well as viscoelastic characteristics such as creep strain, stress relaxation because the matrix of composites become viscoelastic materials in high temperature environment. Thus, thermo-mechanical-viscoelastic effects of the laminated composite structures should be considered for the reliable analysis. As a way to address aforementioned issues, a new type of enhanced analysis model based on the Lo-Christensen-Wu theory (ELCW) in order to accurately predict the viscoelastic behaviors of laminated composite plates under thermo-mechanical loading. In the ELCW, the concepts of the strain energy relationship and Laplace transformation are employed in order to improve the solution accuracy and computational efficiency at the same time.

In this paper, thermo-mechanical-viscoelastic analysis using an enhanced LCW theory (ELCW) will be performed, and the results of the present theory will be compared to those reported in the open literature.

Key Words: *Low earth orbit (LEO), Atomic oxygen (AO) bombardment, Surface recession, Reactive molecular dynamicssimulation, Erosion yield*

Organic polymer-based nanocomposites incorporating nonvolatile inorganic nanoparticles or low-dimensional nanocarbons have long been studied for the spacecrafts and satellites aviating low earth orbit (LEO) and sub-LEO. Against the harsh oxidizing condition attributable for the hyperthermal atomic oxygen (AO) bombardment, mitigation of the surface recession and etching has been the main issue in designing surface shielding materials. In this study, systematic reacitve molecular dynamics (MD) simulations incorporting the reaxFF forcefield were performed to study the hyperthermal erosion of polyimide (PI)-based nanocomposites reinforced with highly thermoprotective inorganic nanofillers. In order to propose optimum reactive simulation condition to mimic the interaction between the nanocomposites surface blanket layer and colliding gaseus atoms or molecule in aviation condition of satellites in LEO, some boundary conditions and thermostatting were tested first. To enable well-developed and steady temperature profile inside the nanocomposites during the bombardment simulation, microcanonical ensemble simulation with a enough thickness of nanocomposites slab more than 4nm was proposed. To prevent the drift of the slab model, during the bombardment simulation, both reflection condition and geomteric constraint at the bottom of the slab models were found desirable.

To descibe the surface recession and temperature rising at the boundary between colliding gases and nanocomposites solid surface, AO particles were collided with a kinetic energy of 4.5eV which corresponds to a typical aviation speed of 7.4km/sec in LEO satellites. As thermoprotective nanofillers both planar and tubular nanostructures were embedded into the PI matrix with a random oritentation. During the bombarmdent simulation, the themperature riging rate and the erosion yield of the nanocompositesx were calculated. With all types of additives studied, a meaningful thermoprotection was achieved in erosion yield and temperature rising rate. Due to the unpaired electrons, AO bombardment showed a sequential disintegration of oxidation and desorption forming volatile oxides. The erosion yield determined from the present reactive MD simulation was compared with the reference value measured from MISSE experiment in international space station (ISS). In addition, the surface recession rate during the hypertmal erosion simulation was determined and corrected to the real aviation speed of the ISS. The corrected surface recession rate determined from the reactive MD simulation was comparable to the in-flight experimental result.

Multiscale model to predict fracture toughness enhancement and fatigue crack growth behavior of polymer nanocomposites

Haolin Wang[1*] and Hyunseong Shin[2]

[1] Department of Mechanical Engineering, Inha University, haolin@inha.edu
[2] Department of Mechanical Engineering, Inha University, shs1106@inha.ac.kr

Key Words: *polymer-matrix composites (PMCs); nanocomposites; fatigue; fracture toughness; toughness mechanisms*

In this study, we develop the multiscale model for the prediction of the fracture toughness enhancement and fatigue crack growth behavior of the polymer nanocomposites (e.g., epoxy/SiC nanocomposites, epoxy/CNF nanocomposites). For the epoxy/SiC nanocomposites, we considered the three main toughening mechanisms (interfacial debonding, subsequent plastic nanovoid growth, and plastic shear band) [1]. For the epoxy/CNF nanocomposites, we considered the other three main toughening mechanisms (interfacial debonding, subsequent plastic nanovoid growth, and pull-out of the CNFs) [2]. To the best of my knowledge, this is the first attempt to develop a multiscale modeling framework by merging all-atomistic molecular dynamics (MD) simulations, micromechanics, and the linear fracture mechanics theory. The predicted fracture toughness and the fatigue crack gorwth of polymer nanocomposites are validated by the comparison with the experimental data. Furthermore, according to our parametric studies, it is clear that the fracture toughness of polymer nanocomposites are rapidly increased as the nanoparticulate diameter decreases.

Key Words: *First-principles calculation, Finite element analysis, Multiphysics, Sodium-ion batteries, Layered-type cathode*

Due to the lower standard redox potential of Na/Na^+, sodium-ion batteries (SIBs) have a limitation on the energy density.[1] To overcome this hurdle, using an anionic redox reaction of O^{2-}/O^{n-} has been highlighted for enlarging the energy density limit of SIBs. To use more energy density from the lattice oxygen redox, most of the sodium-ion needs necessarily to be extracted from the host material, which intrinsically accompanies a large lattice distortion resulting in the irreversible degradation of electrochemical performances.[2] To properly utilize the oxygen redox reaction for the energy density extension, an in-depth understanding of the structural distortion in the primary particle and its effect on the secondary particle is necessary.
In this study, we conduct first-principles calculations to evaluate the lattice change of layered-type $Na_{1-x}[TM]O_2$ in the primary particle. Based on that result, we demonstrate the sodium-ion diffusion and corresponding mechanical behavior in the secondary particle. When the sodium-ions are heavily extracted, layered active materials undergo an abrupt lattice contraction along the out-of-plane direction, which is an inevitable mechanical distortion for layered cathode active materials. This abrupt and anisotropic lattice change causes intergranular damage for the normal secondary particle, resulting in the capacity fading. Therefore, it is important to design the secondary particle that can withstand the structural distortion in the primary particle for enhancing cycle life. Based on the first-principles calculations and the finite element analysis, we give insight into the morphology of the secondary particle to properly withstand the effect of the primary particle lattice distortion.[3]

[3] School of Mechanical Engineering, Chung-Ang University, 84 Heukseok-Ro, Dongjak-Gu, Seoul 06974, Republic of Korea, stchoi@cau.ac.kr

Key Words: *Polymer Pyrolysis, Coarse-grained Molecular Dynamics, Bond Breaking*

Polymer materials can be studied computationally by all-atom (AA) molecular simulations such as molecular dynamics (MD) at a temporal and spatial scale within 100 ns and 10 nm, respectively. In practice some reactive degradation of composites including pyrolysis can take place in much larger scales. For example, due to limitation of time scale, AA MD requires higher temperature for the pyrolysis process to happen in comparison with experimental data [1]. A possible way to extend molecular modelling and bridge it with macroscale computational and experimental techniques is to use coarse-graining: represent a large molecular system efficiently by a reduced number of degrees of freedom. In this study we demonstrate a coarse-grained MD simulation (CGMD) on the pyrolysis of polymer networks under high temperature and atomic oxygen (AO) bombardment.

Polyethylene is considered as an example material for the development of CGMD simulation model with a mapping ratio of 2:1, i.e., two CH_2 groups are represented by one equivalent bead. The CG interaction is described with the DREIDING force field including bonded, angular, torsion and vdW interactions. The bonded interaction can be either Lennard-Jones potential in equilibrium process or Morse potential in pyrolysis process. For the pyrolysis or thermal degradation of polymer networks, the bond breaking phenomenon is implemented in the simulation model, with a criterion based on the critical energy or length of the bond. Because the release of two particles of a broken bond can cause significant disturbance to the system energy, the particles related to bond breaking are relaxed separately with a limited maximum movement.

The parametric studies are performed to investigate the effects of modelling parameters of bond breaking, individual interaction potential, characteristics of oxygen bombardment, etc for the structure-to-property relationship. The results have verified qualitatively that CG MD with bond breaking can be used to capture the pyrolysis process of polymeric systems under hyperthermal reaction condition. In AO bombardment simulation, the energy exchange between gaseous AO and solid surface could be efficiently described by the proposed CGMD simulated. According to the reaction criteria, surface recession and heat transfer was also analysed. The CG MD model developed in this research is helpful to study the pyrolysis of polymer networks at larger scales to reduce the gap between simulation and experiment of these complex processes.

[4] Chung-Ang University, Seoul 06974, fafala@cau.ac.kr

Key Words: *Reactive molecular dynamics simulation, Pyrolysis, Thermal protective nano composites, Activation energy*

In this study, thermo-resistant properties of polyimide and polyimide/inorganic nano particulate composites are investigated by reactive molecular dynamics (ReaxFF MD) simulations. Thermal protective polyimide (TPI) and polyimide-based thermal protective nanocomposites (TPN) used for satellites and ballistic missiles undergo pyrolysis and ablation in ultra-high temperature environment, effectively blocking the heat transferred to the nose cone and fuselage. The most representative method to evaluate the thermo-resistant properties of TPI and TPN is to determine the activation energy by applying the relationship of temperature-reaction rate constant to the Arrhenius equation. In this study, to obtain the activation energy of TPI and TPN, ReaxFF MD simulations were executed under various temperature conditions, and then the relationship of reaction time-thermal decomposition was handled. In order to establish reaction time-to-thermal decomposition relationship of TPI and TPN, two different post-processing methods were used to define the rate constant of the pyrolysis: number of undecomposed chain-based and mass loss-based approaches. The activation energies determined from the two different pyrolysis criteria were compared with each other. In addition, to characterize the properties of soot produced after the pyrolysis, uniaxial tension simulations of carbon network structures remaining after the thermal decomposition simulations were performed. Due to the carbon network structure, the soot layer has very high stiffness compared with unreacted neat polyimide. To validate the activation energy-based thermal resistant property evaluation method, AO (Atomic Oxygen) bombardment simulations were implemented to mimic the in-flight ablation of the TPN. The erosion yield and temperature rising rate of the nanocomposites determined from AO bombardment simulations were qualitatively compared with the activation energy of each nanocomposites structures.

Key Words: *Temporal Homogenization; Multiscale modeling; Viscoelastic; Viscoplastic; Cyclic loading*

In this study, the temporal homogenization formulation is developed to predict the response field (e.g., stress, strain, displacement) of the viscoelastic-viscoplastic materials subjected to locally periodic loading. This study is first attempt to apply the temporal homogenization formulation of higher order differential form of the constitutive equation on the viscoelastic-viscoplastic materials. The temporal homogenization formulation is defined two types: the non-updated temporal homogenization formulation and the updated temporal homogenization formulation. In conclusion, the initial boundary value problems are divided into macro-, micro-chronological term. For the verification of this approach, there are two examples: (i) uniaxial cyclic loading on one-dimensional bar, (ii) multiaxial cyclic loading on three-dimensional bar. Comparing the accuracy of the non-updated temporal homogenization formulation and the updated temporal homogenization formulation, it can be clearly seen that the updated temporal homogenization formulation obtained more accurate results.

Key Words: *Boron Nitride, Molecular Dynamics Simulation, Viscoelastic, Damping coefficient, Quality Factor, Interface*

In this study, molecular dynamics (MD) simulations approach to predict the viscoelastic behavior of boron nitride nanotube (BNNT) polymer nanocomposites is demonstrated. In order to characterize damping coefficient of BNNT polymer nanocomposites, a repeated cyclic loading is applied to the periodic unit cell structure. During the wiggling test, the stored energy and dissipated energy were monitored to determine the quality factor (Q factor) and damping ratio. Some structural defects such as mono- and di-vacancy are considered to understand how imperfections in BNNT affects the interface characteristics and the resultant damping coefficient. At the same time, viscoelastic moduli of nanocomposites were determined from sinusoidal variation of the applied strain and the resultant stress. During the wiggling test, the storage modulus and loss modulus were determined from phase lag between stress and strain which occurs from internal damping. The results show that the Q factor decreases with increasing the driving angular frequency. As the number of defect increases, the damping characteristics and the viscoelastic moduli of nanocomposites were affected by the interface condition as well as the decrease of BNNT's properties in a complicated manner. The possibility of defect engineering to tailor the viscoelastic damping characteristics of BNNT polymer nanocomposites was also discussed.

Key Words: 3D global transport model, cubed-sphere grid, multi-moment method, semi-Lagrangian method, mass conservation, positive definite

A three dimensional positivity-preserving and conservative multi-moment transport problem on the cubed-sphere grid was proposed. The numerical solution was calculated by using the dimensional splitting technology to update the horizontal and vertical direction separately. The horizontal direction was updated by the three-point high order multi-moment finite volume method with boundary gradient switching technology, and the vertical direction was updated by the conservative multi-moment semi-Lagrangian (SL) method with the piecewise rational function as spatial reconstruction profile. Some corrections were also involved to ensure a positive numerical result. To evaluate the performance of the proposed model, the transport test cases in the Dynamical Core Model Intercomparison Project were conducted. The numerical test results showed that the model was inherently conservative, non-oscillatory and positivity-preserving. Compared with other existing models in the literature, the proposed model was quite competitive. Furthermore, the semi-Lagrangian method in vertical direction can effcetively avoid the CFL restriction problem caused by the dense vertical grid mesh in real atmopsheric model, which is attractive for practical application in full weather or climate model.

A High-Fidelity Physics-Based Approach for Space Weather Modeling

Jordi Vila-Pérez[1*], Ngoc-Cuong Nguyen[2] and Jaime Peraire[3]

Massachusetts Institute of Technology, 77 Massachusetts Ave, 02139, Cambridge, MA, USA
[1] jvilap@mit.edu, [2] cuongng@mit.edu, [3] peraire@mit.edu

Key Words: space weather, physics-based model, high-order discontinuous Galerkin, GPU

Empirical models of the Earth's atmosphere have been traditionally used to understand the system response to different space weather events based on observational data [1]. However, their limited forecasting capability, specially given the sparse data availability, has prompted in recent years the development of a number of physics-based models, such as the global ionosphere-thermosphere model (GITM) [2], which offer improved prediction capabilities. Their advanced modeling properties, though, come at a high computational cost: solving nonlinear and very high-dimensional systems of conservation laws over long intervals of time.

For this reason, this work presents a high-fidelity physics-based approach for the simulation of space weather on graphic processors (GPUs). The proposed model of the Earth's ionosphere-thermosphere describes an atmosphere in non-hydrostatic equilibrium, driven by the external excitation of solar extreme ultraviolet (EUV) radiation. The conservation equations of continuity, momentum and energy are equipped with realistic data-driven source terms to model heat transfer effects. Moreover, the multiscale variations of the different physical quantities in the radial and angular directions are managed in a fully coupled description, introducing a proper scaling to the momentum and energy variables, and the logarithm of the density as a primary variable to handle the low densities present at high altitudes.

The system is solved using a high-order implicit discontinuous Galerkin (DG) method on unstructured adapted meshes combined with diagonally implicit Runge-Kutta (DIRK) schemes. The numerical discretization is combined with a Jacobian-free Newton-Krylov strategy and matrix-free preconditioners suited to perform on GPU architectures [3, 4]. The proposed method is validated by means of a series of numerical benchmarks and compared to existing reference solutions.

Key Words: Moving interface, Quartic surface polynomial, Volume of fluid, Level set, THINC, Unstructured meshes

In this paper, we developed a hybrid volume of fluid (VOF) and level set interface capturing scheme with quartic surface representation for unstructured meshes. The so-called THINC-scaling scheme with quartic surface representation (THINC-scaling/QSR) preserves the merits of the mass/volume conservativeness from the VOF scheme along with the geometric faithfulness from the level set scheme. Compared with linear/quadratic surface representation used in many other interface capturing schemes, the fluid interface is defined more precisely as a quartic polynomial surface of THINC function which synchronize the interface between the VOF and level set function in a straightforward solution procedure. We update the VOF function using a finite volume formulation. The level set function is first locally updated via a semi-Lagrangian method for interface cells and then reinitialized within each time step. Multi-dimensional algorithm has been developed and verified by some benchmark tests on unstructured meshes. Convincing evidence suggests that the present scheme, with quartic surface representation, can provide high-fidelity solution with more pronounced sub-grid interface capturing capability than other most advanced methods.

Key Words: *multi-moment scheme, tracer advection, nonhydrostatic model*

A moist nonhydrostaic atmospheric model is developed by using a 3-point multimoment constrained finite-volume (MCV) method. The MCV scheme is local reconstructed scheme like DG and spectral element schemes and can achieve high accuracy. The model variables are the pointwise values of the physical fields located at the equidistant solution points. The constraint on the volume-integrated average (VIA) rigorously guarantees the numerical conservation. The tracer advection is key process for transporting the vapor and precipitation in the real atmosphere. To suppress the unphysical noises for tracers, the non-oscillatory limiter has been adopted in the present model. The resulting model is validated by a well-established benchmark test and compared with the existing compressible model.

A Non-Negativity Preserving Transport Model Using Multi-Moment Finite-Volume Method and Icosahedral-hexagonal Grid

Zhao Yanfeng[1*] and Chen Chungang[1]

[1*] Xi'an Jiaotong University, Xi'an 710049, China, zhaoyf@stu.xjtu.edu.cn

Key Words: *Non-negativity Scheme, Multi-moment Method, Transport Model, Icosahedral-hexagonal Grid*

A global transport model with non-negativity property was developed by implementing the high order multi-moment finite volume method [1] on icosahedral-hexagonal grid. Our previous studies have shown that the transport model on icosahedral-hexagonal grid has rigorous numerical conservation and third-order accuracy [2], however, the non-negative numerical solution is not guaranteed and nonphysical undershoots are existed in the numerical results, which violates the physical principle.

Two kinds of moments, including the volume-integrated average (VIA) and the point values (PV), are adopted in the multi-moment scheme and this study is focused on assuring the non-negativity of the VIA moment. The negative solutions of PV moments can be directly removed with destroying the numerical conservation. As the spatial discretization of the VIA is accomplished by evaluating the numerical fluxes along the cell edges, a upper limit on the mass leaving the cell, which is found following the basic idea of the Flux-Corrected-Transport (FCT) method [3] proposed by Smolarkiewicz in 1989 , is adopted to impose the restriction on the numerical fluxes. In one dimensional case, the FCT scheme can be straightforwardly applied by revising the values of PV moments defined at cell interfaces. In multi-dimensional case, the numerical fluxes across the cell edges are determined by more than one PVs and each PV defined at cell vertices are involved in calculations of two numerical fluxes in our multi-moment model[4]. As a result, a new flux correction algorithm was designed on two-dimensional icosahedral-hexagonal grid to develop a global non-negative multi-moment transport model.

The proposed non-negative numerical scheme on icosahedral-hexagonal grid is validated by widely used benchmark tests and the numerical results reveal that the non-negativity of the numerical solutions is guaranteed while the high-order accuracy is preserved. The proposed model provides a promising and practical framework for further development of three-dimensional transport models for dynamical cores on icosahedral-hexagonal grids.

Key Words: *Multi-moment method, Dynamical core, Nonhydrostatic model, Global model, cubed-sphere grid.*

As one of key components of the atmospheric genernal circulation models, the dynamical core solves the Navier-Stokes equations on a rotating sphere. To construct the high-resolution numerical models for weather and climate predication, great efforts have been paid recently to improve the dynamcial core, mainly considering its mesh quality, discretization accuracy, computational efficiency, model rebustness and so on.

A nonhydrostatic dynamical core has been developed by using the multi-moment finite volume method that ensures the rigorous numerical conservation in this study. To represent the spherical geometry free of polar problems, the cubed-sphere grid is adopted. A fourth-order multi-moment discretization formulation [1] is applied to the nonhydrostatic governing equations cast in local curvilinear coordinates on each patch of cubed sphere through a gnomonic projection. In vertical direction, the height-based terrain-following grid is used to represent the topography. To get rid of the CFL stability restriction imposed by relatively small grid spacing in the vertical direction, the dimensional-splitting time integration using the HEVI (Horizontal Explicit and Vertical Implicit) strategy is implemented by applying the IMEX Runge-Kutta scheme.

The proposed dynamical core has been extensively verified by the widely-used benchmark tests [2] in comparison with other existing dynamical cores. The results of our numerical experiments show that the present numerical framework has superior solution quality and great practical potential as a platform for atmospheric models. A new unified model for numerical weather prediction and global atmospheric circulation simulation based on this dynamical core is under development in CMA.

Key Words: Multi-phase flow, THINC/QQ, VOF, Interface capturing, AMR, Supercavitation

Numerical simulations of multi-phase flows involving immiscible interfaces are an active research topic with great importance in a wide variety of environmental, industrial and engineering applications. However, the numerical modeling of interfacial multi-phase flows is fraught with challenges that are inherently complicated in handling the topologically changing interfaces between the two phases, particularly for the unstructured grids. In this talk, we revisit to THINC/QQ (Tangent of Hyperbola INterface Capturing methods with Quadratic surface representation and Gaussian Quadrature)[1] and presents some recent progresses made extensively to improve numerical accuracy and robustness. Then, we develop accurate and efficient solvers for interfacial multi-phase flows based on the framework of OpenFOAM by combining it with PISO (Pressure Implicit with Splitting of Operators) algorithm, as well as AMR (Adaptive Meshes Refinement) techniques. Furthermore, we also develop high-fidelity numerical solvers for turbulent cavitation flows based on the homogeneous equilibrium model. The so-called thincFoam is versatile and potent, offering sufficiently high accuracy for practical applications.

Two and three-dimensional benchmark tests are carried out by solving VOF advection equation on different type of grids. It is convinced that the proposed THINC/QQ scheme shows superior numerical accuracy, robustness and boundedness than original one, and is competitive to the other state-of-art VOF methods. We present some numerical examples such as dam break, bubble rising and RT instability to evaluate the performance of multiphase solver. The numerical results are in excellent agreement with the experimental data and analytical solutions, and show significant improvements in solution accuracy and computational efficiency compared with those of interFoam. Additionally, supercavitation simulations are carried out around an axisymmetric projectile and a conical cavitator at different cavitation number. Our results demonstrate much less numerical sensitivity and solution dependency on the different choice of turbulence and mass transfer models. We believe that the present solvers will be one of the attractive choices in the high-fidelity simulations of multiphase flows involving complex geometries.

An Adaptive Global Nonhydrostatic Atmospheric Dynamical Core on Cubed Sphere Using Multi-Moment Constrained Finite Volume Method

Huang Pei[1*] and Chen Chungang[1]

[1*] Xi'an Jiaotong University, Xi'an 710049, China, hp2813@stu.xjtu.edu.cn
[1] Xi'an Jiaotong University, Xi'an 710049, China, cgchen@xjtu.edu.cn

Key Words: *Adaptive Mesh Refinement, Nonhydrostatic Atmospheric Model, Dynamical Core, Multi-Moment Constrained Finite-Volume Scheme*

An adaptive 3D global nonhydrostatic dynamical core is proposed on cubed-sphere grid, using the multi-moment constrained finite-volume (MCV) scheme [1] and the Berger-Oliger adaptive mesh refinement (AMR) algorithm [2]. As a newly developed high-order method, the MCV scheme is featured by compact reconstruction stencil and rigorous numerical conservation constrained by the updating of the volume-integrated average (VIA) moment.

The AMR grid of Berger-Oliger includes several groups of grids with different resolutions. During a simulation, refined grids are generated adaptively according to the structure of flow field. Each grid is defined independently and it can be discretized and integrated directly by the same MCV scheme. This makes the extension to the cubed-sphere grid easier as the curvilinear coordinates on each patch of the cubed-sphere are structured. Efforts are mainly spent on the designs of numerical formulations for the coarse-fine interpolation and the flux correction for properly exchanging the solution information among grids of different levels and patches. Considering the fact that the global atmospheric dynamics is mostly dominated by horizontal motions, AMR procedure is only applied in horizontal directions in this study, though no technical problem in generalizing it to a 3D case exist. To avoid impractical small time step restricted by the very large ratio between the horizontal and the vertical grid spacing, the implicit-explicit (IMEX) Runge-Kutta method [3] is introduced as time-marching scheme. The vertical-related terms are advanced by implicit time integration and available time step will be determined only by stability condition in the horizontal directions.

Typical benchmark tests with topography are carried out to evaluate the proposed model. The numerical results on uniform and AMR grids reveal the effectiveness of the AMR technique in saving computational costs, and the accuracy on uniform grid is largely maintained when adaptive grids are implemented. More and more attention being paid to the finer predictions of small-scale weather phenomena has led to a huge demand for computing resources. Using AMR grids, these spatially complex small-scale phenomena are fully described with as few computing resources as possible, thus it is promising to develop an efficient practical atmospheric core under the proposed adaptive framework.

ABSTRACT

A meshfree/meshless method is a powerful computational tool in continuum mechanics in various physics, engineering, and biological problems. Especially, the methods based on a strong formulation are practically useful that is a complete mesh free [1]. However, in general, the meshless methods tend to be computationally expensive compared to mesh/grid-based methods. That arises from increasing the computational cost to find neighboring calculation/discretization points in gradient calculations using randomly distributed configuration even if applying background meshes (or buckets) approach. In addition, for an implementation to parallel computing with domain decomposition, it is necessary to make a large effort to maintain the computation load per parallelization node evenly. Moreover, in the meshfree methods based on a Lagrangian description (e.g., [2]), the discrete point positions are updated in every timestep and frequently update bucket information with non-uniform internode communication. Therefore, the development of more practical and efficient meshless methods promises to be useful in large-scale simulations.

In this study, we develop a novel discretization scheme for continuum analyses using a mesh-constrained discretization point formulation that becomes a hybrid approach using the meshless and mesh-based ideas. In the present method, discrete points are introduced in background meshes and re-distributed so as to fit arbitrary boundary shapes, where the points are completely confined in (or constrained by) each corresponding background mesh. This allows to efficiently calculate spatial gradients using the MLS approximation [3] and capability in high efficiency in large-scale parallel computation. The method was validated through a numerical example for the two-dimensional Taylor-Couette flow.

Key Words: *Isolated element method, Node-less element, Variational principle, Rigid body displacement, Upper and lower bounds, Finite element method*

A new discretization analysis method named the isolated element method [1], that differ from conventional FEM, for solid mechanical problems is proposed. An object to be analyzed is divided into the elements that are separated from each other. A set of displacement functions providing arbitrary number of degrees of freedom is used for each isolated element which expresses the translation and rotation of a rigid body. The extended principle of minimum potential energy is applied to satisfy the continuity of the displacement of isolated elements adjoining to each other. Any node or spring, penalty functions and Lagrange multipliers are not used in this method. The displacement functions of the power series are used to describe the mechanical state of the isolated element and finally, the coefficients of series are determined by a variational principle derived from the extended principle of minimum potential energy.

Furthermore, a new mixed and hybrid variational principle [2] which is composed from the potential and the complemental energy functional is proposed. The pair of these energy are constrained by a formula. Using this new principle, in which stress and displacement can be used as independent variables, the stress and displacement are computed at the same time. Besides, upper and lower bounds solutions are analyzed using the new principle and the isolated element method.

Some computed examples of the plane stress problems are presented. We show the good convergency of the numerical results, and also present the upper and lower bound results of stress and displacement by the new mixed and hybrid variational principle using the isolated element method

Key Words: Compressible folws, Discontinuities, Low-dissipation, BVD schemes, Unstructured grids

Compressible flows containing both discontinious and smooth structures are widely encountered in practical problems, such as aerospace engineering, internal combustion engine, energy and chemical industries, to name but a few. It still remains a great challenge for finite volume schemes to numerically solving such complex flows on unstructured grids, where implementing low-dissipative limiting procedure to suppress numerical oscillation faces many difficulties. As a result, most of the unstructured finite volume method for compressible flows are constructed based on second-order schemes which are too dissipative to resolve fine structures such as shockes, interfaces and vorticities. In this talk, we propose a novel hybrid scheme to resolve discontinuities and smooth structures on hybrid unstructured grids. Numerical dissipation is reduced by adaptively choosing appropriate reconstruction scheme based on the one-step Boundary Variation Diminishing (BVD) algorithm[1]. As a results, the MUSCL (Monotone Upstream-centered Schemes for Conservation law) scheme with the MLP slope limiter[2] is adopted to solve smooth regions, while the multi-dimensional THINC/QQ scheme[3] is used to mimic the discontinious solution. The so-called MUSCL-THINC/QQ-BVD scheme is algorithmically simple and shows great superiority compared with other existing schemes for compressible flows on unstructured grids. The performance of present scheme has been extensively verified through benchmark tests of single and multi-phase compressible flows.The numerical results show that the proposed solvers developed upon MUSCL-THINC/QQ-BVD scheme are capable of capturing sharp discontinuous profiles without numerical oscillations and resolving vortical structures along shear layers and material interfaces with solution quality superior to other schemes of second and even higher order.

Large-eddy Simulation of Turbulent Flows over Sphere Based on High-order Schemes

Peng Jiang[1,*], Bin Xie[1], Shijun Liao[1]

[1] Shanghai Jiao Tong University, Shanghai, 200240, China.
E-mail: sjtu-jp@sjtu.edu.cn (P. Jiang); xie.b.aa@sjtu.edu.cn (B. Xie);
sjliao@sjtu.edu.cn (S.J. Liao).

Key Words: High-order schemes, Turbulent flows, LES, Sub-critical Reynolds numbers

As arguably the most basic three dimensional geometry, the sphere is considered as an excellent prototype for understanding the wake flows of more general bluff bodies in the engineering applications. In the present study, large-eddy simulations are carried out to investigate unsteady flows around a sphere at sub-critical Reynolds numbers (Re, based on the diameter of the sphere and the freestream velocity). In order to sufficiently capture the turbulence structure, we develop a high-fidelity numerical model for incompressible flows on the unstructured grids which is constructed based on implicit discretization of FVMS3 [1] (Finite Volume method based on Merged Stencil with 3rd-order reconstruction) scheme and fraction-step approach for pressure-velocity coupling.

The performance of this model is first verified by the benchmark test of the steady and unsteady laminar flow at Reynolds numbers of up to 300. The results of hydrodynamic forces, local pressures, and near-wake structures computed by the present solver is examined with adequate solution quality compared with experimental records. In addition, A highly organized flow dominated by periodic vortex shedding, the hairpin vortices has been observed at $Re = 300$, also in good agreement with previous work. After validation, for flow around a sphere at $Re = 1 \times 10^4$, the spatial and temporal features of flow structures at different scales were further explored with respect to mesh type (hexahedra, polyhedra, tetrahedra, and prisms). Special attention is devoted to assessing the prediction of the statistical properties of turbulence, such as wall-pressure distribution, skin friction, and drag coefficient, in order to test the present LES closure model. After conducting comparative study, the present numerical framework shows significant improvements in solution accuracy and numerical robustness over conventional second-order schemes. Moreover, coherent structures of turbulent wake and turbulent kinetic energy (TKE) balance, i.e. the production and dissipation of TKE are also investigated to demonstrate the solver's applicability in different and complex mesh topology.

Key Words: *Lattice Boltzmann Method, Large-Eddy Simulation, Particle Filter, Adaptive Mesh Refinement*

This paper presents a novel data assimilation method in realistic turbulent boundary layer simulations for the realization of a wind digital twin. We have developed a plume dispersion simulation code named CityLBM based on a lattice Boltzmann method (LBM). CityLBM enables a real time ensemble simulation for several km square area by applying locally mesh-refinement method on GPU supercomputers [1]. We validated CityLBM against plume dispersion experiments in the complex urban environment of Oklahoma City (JU2003, Leach 2005). Mesoscale wind boundary conditions of JU2003 produced by a Weather Research and Forecasting Model (WRF) were given as boundary conditions in CityLBM by using a nudging data assimilation method (Paniconi et al. 2003; Brian et al. 2010). The statistics of the ensemble-averaged concentration values for ~70% of the monitoring data satisfied factor 2 agreements [2].

Although the above validation study was focusing on the expeiments conducted in the morning on July 16, the experiments in the afternoon have been yet to be validated. In the previous study, the coefficient of the nudging data assimilation method, which characterizes the mixture ratio between turbulent flows from the periodic boundary and laminar flows from the WRF data, was optimized for the statistics of turbulent intensity in the morning. However, the same nudging coefficient lead to an overestimation of the turbulence intensity in the afternoon due to atmospheric instability caused by the increased ground temperature. To resolve this issue, we propose a dynamic nudging data assimilation method, where a particle filter optimizes the nudging coefficient based on the observation data. Here, different nudging coefficients are assigned to each ensemble calculation, and are updated to reduce the error of the turbulence intensity between the simulation data and the observation data every 15 minutes. This approach gave reasonable agreements in vertical profiles of the wind speed, the wind direction, and the turbulent intensity compared to the observation data throughout the day, and enabled all-day simulations, where atmospheric conditions change significantly. In this presentation, we will also report the improvement of concentration predictions in the afternoon.

The application of Piecewise Rational Method in scalar advection of GRAPES

Su Yong[1*] Shen Xueshun[2]

[1] Center for Earth system Modeling and prediction of CMA (CEMC), Beijing 100081, suyong@cma.gov.cn

[2] Center for Earth system Modeling and prediction of CMA (CEMC), Beijing 100081, shenxs@cma.gov.cn

Keywords: *PRM, scalar advection, GRAPES, semi-lagrangian*

How to better simulate the advection and the distribution of water substance, is of great significance for the improvement of numerical weather prediction, especially for precipitation. The computation of advection process in a semi-lagrangian model requires high accuracy, conservation of mass, positive and preserve of shape. But the QMSL (Quasi-Monotone Semi-Lagrangian) scheme which adopted in GRAPES (Global and Regional Assimilation & Prediction System) suffers a lower accuracy in the strong gradient and discontinuity regional of the scalar field, and cannot be strictly conserved the mass.

This study draws on research progress in the field of computational fluid dynamics, introduce a material advection scheme PRM (Piecewise Rational Method) which based on piecewise continuous rational function into GRAPES, solve the water vapor equation in the flux form, and treat the polar regions with a mix technical. The two advection schemes were compared by a series of stand-alone and in-model ideal test, proofed that compare to QMSL scheme, PRM scheme is of higher precision, especially in the area of large water vapor gradient, the dispersion and dissipation error is smaller, the conservation and shape preserving is also better. Through the examine of batch prediction experiments in GRAPES, verified that the PRM scheme can effectively improve the simulation of the advection and distribution of water substance, promote the effect of precipitation forecast, and also plays a significant role to the enhancement of the comprehensive model performance.

At present, a series of prediction systems based on GRAPES dynamic core adopted this advection algorithm in CMA, including GRAPES_GFS (global, 25km), GRAPES_MESO (China, 10km), GRAPES_MESO_3km (China, 3km), GRAPES_TYM (Indian Ocean and Northwest Pacific, 9km), GRAPES_GEPS (global, 50km), etc.

Abstract
Strain localization analysis based on finite element method (FEM) usually requires an intensive computation to capture an accurate shear band and the limit stress, especially in the heterogeneous problems, and thus costs much computational resource and time. This paper proposes an adaptive multiscale FEM (AMsFEM) to improve the computational efficiency of strain localization analysis in heterogeneous solids. In the multiscale analysis, h- and p-adaptive strategies are proposed to update the fine and coarse meshes, respectively. The problem of mesh dependence is handled by the Cosserat continuum theory. In the fine-scale adaptive procedure, triangular elements are taken to discretize the fine-scale domain, and the newest vertex bisection is utilized for refinement based on the gradient of displacement. In the coarse-scale adaptive procedure, a multi-node coarse element technique is considered. By introducing a probability density function for each side of a coarse element, the optimal positions of the newly added coarse nodes can be determined. With the proposed adaptive multiscale procedure, the computational DOFs are reduced smartly and massively. Three representative heterogeneous examples demonstrate that the proposed method can accurately capture shear bands, with an improved computational efficiency and robust convergence.

Modeling the Amorphous Polymers Behavior from Low to High Strain Rates

A. Francisca C. Alves [1*], Bernardo P. Ferreira [1] and F. M. Andrade Pires [1]

[1] DeMec, Faculty of Engineering, University of Porto, {afalves, bpferreira, fpires}@fe.up.pt

Key Words: *Amorphous Polymers, Constitutive Model, High Strain Rate, Material Parameters Calibration, Multiscale Modeling, Computational Homogenization*

Amorphous polymers find their main application in the military, automotive and aerospace industries where different loading conditions, such as strain rate, temperature, and pressure, are essential. Typically, polycarbonate (PC) and poly(methyl methacrylate) (PMMA) are used in high strain rate applications due to their lightweight and transparency properties, as well as for their toughness and impact resistance. Through the combination of the excellent thermal and mechanical properties of PC and impact properties of ABS, the rubber toughened ternary blend PC/ABS is one of the most successful commercial polymer blends. The understanding of their multiscale behavior is fundamental for developing new products and enhanced materials, capable of responding to the ever-increasing industrial demand.

The intrinsic behavior of amorphous polymers is known to be extremely sensitive to both temperature and strain rate. While an increase in strain rate promotes an increase of stress, an increase in temperature has the opposite effect. Based on experimental results over a wide range of temperatures and strain rates, Bauwens-Crowet [1] observed that the stress increase is more prominent at higher strain rates (or lower temperatures) than it is at lower strain rates (or more elevated temperatures). This phenomenon has been attributed to the activation of a particular molecular mobility, called the β-transition [2].

In the present contribution, we extend the modified Eindhoven Glassy Polymer (EGP) model proposed by Mirkhalaf et al. [3] to predict the thermomechanical behavior of glassy polymers throughout a wide range of strain rates. The predictive capability of the extended model is assessed by comparing its numerical response with experimental data and different state-of-the-art constitutive models for PC and PMMA, and different loading conditions. In addition, the homogenized thermomechanical behavior of the PC/ABS polymer blend at high strain rates is inferred by conducting first-order hierarchical multiscale analyses based on computational homogenization. State-of-the-art optimization algorithms are explored to speed up the identification of the model's material parameters.

Key Words: Transformation-induced plasticity, Crystal plasticity, Multi-scale, Parameter identification

The combination of high strength and ductility in metals has been pursued in the last decades, leading to the development of steels such as TRIP (transformation induced plasticity). Modelling the macroscopic response of such materials requires the delicate handling of several complex microscopic phenomena, namely slip plasticity and austenite-to-martensite mechanical transformations. Multi-scale models are well-suited for capturing this interplay of mechanisms by directly modelling the microscopic response of each constituent within a polycrystalline Representative Volume Element (RVE).

A fully implicit constitutive model for austenite-to-martensite transformation with coupled austenite slip plasticity, phase transformation and martensite slip plasticity is used in this work [1]. The generalisation of Patel and Cohen's energy-based criterion introduces the effect of mechanically-induced martensitic transformation, coupled with a volume-preserving exponential mapping integrator for slip plasticity in both austenitic and martensitic phases. A rate-dependent regularisation is employed and several numerical techniques are explored to improve the robustness and efficiency in the rate-independent limit.

Parameter identification is a critical step in model validation. Some parameters are related to physical quantities that can be measured, while others can only be found by trial and error. This work describes a method for automatic parameter identification for macro, micro and constitutive responses using multi-objective derivative-free optimisation methods. With this tool, the accuracy and validity of the proposed constitutive model is studied, using experimental and numerical results in the literature (for instance [3]).

Size Effects in Fully Second-Order Computational Homogenisation

Igor A. Rodrigues Lopes[1*] **and Francisco M. Andrade Pires**[1]

[1] Faculty of Engineering, University of Porto, Porto, Portugal, {ilopes;fpires}@fe.up.pt

Key Words: Multi-Scale, Second-Order Computational Homogenisation, Finite Element Method, Size Effects

Multi-scale models based on fully second-order computational homogenisation [1, 2], where second gradient continuum is considered at both the macro and micro-scales, are able to capture size effects due to the micro-constituents. This fact arises from the length scale parameter introduced by considering second gradient constitutive modelling at the micro-scale. This contrasts with standard second-order homogenisation [3], where size effects are only related to the length of the Representative Volume Element (RVE).

In the present contribution, a fully second-order computational homogenisation model at finite strains is presented. Mixed finite elements are employed at both scales to deal with the C^1 continuity requirement. The Method of Multi-Scale Virtual Power is followed to develop the multi-scale formulation in a variationally consistent fashion and Lagrange multipliers are introduced to enforce the boundary conditions on the RVE. An efficient strategy is devised to compute the macroscopic tangents required for coupled-scale FE^2 simulations. Numerical FE^2 experiments of a boundary shear layer are employed to assess size effects introduced by this kind of multi-scale formulation, due to both the RVE length and the micro-constituents' length scale parameter.

Key Words: *Large Intestine, Stent Treatment, Finite element method*

A stent is used to treat obstructive colorectal cancer. A stent is a mesh- or tube-shaped medical device made of shape memory alloy. If the stent deployment force is not appropriate, complications such as perforation of the colon and stent dislodgement may occur. In addition, it has been suggested that excessive deployment force in the colon may accelerate cancer metastasis. Therefore, for the development of safer colonic stents, it is important to evaluate not only the deployment force of the stent but also the stress-strain distribution in the cancer and healthy large intestine during stent deployment. However, it is not possible to directly measure the stress and strain distribution in the cancer and the intestine.

The purpose of this study is numerical stress-strain evaluation of the intestine cancer under stent treatment using a finite element method. This paper will present the following topics:

- Material modelling of healthy and cancerous part of large intestine
- Determination of element discretization conditions for high-precision finite element analysis
- Numerical experiments to predict stress and strain distributions under stent treatment with several heights and hardnesses cancers

Abstract: Objective: To analyse the biomechanical characteristics of acetabular internal fixation system for the treatment of complex acetabular fractures and evaluate its effect, and to explore the relationship between internal fixation and the healed bone, so as to provide guidance and theoretical basis for the accurate treatment of acetabular fractures. **Methods:** Based on the CT scan data of the pelvis of a patient cured by acetabular internal fixation system, a healed pelvic model with internal fixators was established by three-dimensional reconstruction technique, and the spring element was used to simulate the main ligaments of the pelvis, and the finite element analysis was carried out under the load condition of gait phase. Through the relevant mechanical indexes such as displacement and stress, the stability of the pelvis and the stress diversion between the acetabulum and the internal fixators were analysed, and the strain energy distribution of the acetabular three columns was analysed according to the acetabular three-column theory. **Results:** Under the combined condition of gait cycle, the displacement of the left acetabulum and the right acetabulum are small, and the stress distribution is similar to that of the normal acetabulum, and the average stress difference between the internal fixation system and the bone is within a certain range. In the whole gait cycle, the strain energy of the central column of the acetabular three-column is relatively large in the support phase, while the strain energy ratio of the anterior column and posterior column of the acetabular three-column increases in the swing phase. **Conclusion:** The acetabular internal fixation system designed according to the anatomical characteristics of the acetabulum and the acetabular three-column theory not only provides effective mechanical support for the good reduction and stable fixation of the fracture, but also conforms to the natural force flow of the bone. the internal fixators are integrated into the normal physiological stress conduction of the pelvis.

Key Words: ARDS, Pulmonary hypertension, CFD, CNN (Convolutional neural network), Covid-19

The clinical definition of ARDS in adults is "Rapid onset of noncardiogenic pulmonary edema", which is an abnormal accumulation of fluid in the extravascular compartments of the lungs. The hemodynamic instability is a primary factor influencing mortality and the mortality rate among COVID-19 ARDS ventilated patients is one of the most disheartening published results in 2020. The important question is, can we correlate flow alterations and ARDS and come up with the good predictors.

The purpose of this study is to characterize flow patterns and several other hemodynamic parameters (WSS, OSI, Helicity) using computational fluid dynamics model by combining imaging data from 4D-Flow MRI with hemodynamic pressure and flow waveforms from control and hypertensive subjects (related to acute respiratory distress syndrome).

A realistic and automated segmented geometry of pulmonary artery for mechanically ventilated conditions (Baseline, ARDS, Optimal Lung Approach, Hyperinflation and Collapse) is obtained by training a (2D convolutional neural network) (CNN) on CTA scans obtained by translating MRA images. Fluid dynamics equations are solved for the subject specific pulmonary arterial meshes. This work considers the utility of computational models in providing insights into identifying abnormal flow features of the pulmonary circulation, and their application in clinically motivated studies related to ARDS.

Specific attention is devoted to mutual validation of quantitative parameters generated from CFD and PC-MRI images. So far, the analysis is done on six subject with five ventilatory conditions(Basal, ARDS, OLA, HI, COL). Different hemodynamic parameters are analysed after in-vivo validation of velocity profiles and then important predictors is presented after statistical validation. This work mainly concerns how to facilitate bench-bedside approach using CFD tools and is a continuation of our previous work with diseased cases.

Key Words: *Finite element analysis (FEA); Computational fluid dynamics (CFD); Carotid artery stenting (CAS); Nitinol; Stent; Membrane; Covered Stent; Infolding*

Carotid endarterectomy (CEA) is the gold standard preventative treatment for high-grade carotid artery stenosis. However, CEA is invasive and often associated with a higher risk of ipsilateral stroke and death. Recently carotid artery stenting (CAS) has emerged as an attractive alternative due to its less invasive procedure that can help to prevent stroke in patients with carotid artery stenosis. But stenting using bare-metal stent is poor in preventing the detached plaque into cereal circulation. A covered stent can provide better protection to avoid thrombosis. However, the conventional dip-coating method may trigger the membrane infolding in the covered stent that was found to affect the mechanical performance of the covered stent in the artery.

To minimize the effect of membrane infolding, we have proposed a new coating method by pre-crimping the covered stent before coating. Detailed structural analyses were performed on the conventional dip-coating method and the proposed new method. A multi-step simulation was performed on the covered stent to evaluate the stress distribution across the covered stent. In addition, we also investigated the hemodynamic behaviour of the covered stent using computational fluid dynamics (CFD) to evaluate the risk of thrombosis after deployment. Non-Newtonian fluid model and realistic boundary conditions were used in the current study to model the realistic blood flow behaviour.

The higher von Mises stress was found in the membrane of the covered stent manufactured by the conventional dip-coating method after infolding occurred, compared to the new method in the structural mechanics analysis. Our new pre-crimped coating method minimised the deformation as examined in our computational study, followed by experimental testing. CFD results showed that our new pre-crimped covered stent could reduce the risk of thrombosis compared to the conventional coating method. No platelet activation was found in the animal experiment using our pre-crimped covered stent compared to the conventional dip-coating method. Both computational and experimental results showed satisfactory mechanical performance in mitigating infolding of covered stent.

In conclusion, our study showed that our new coating method is better than the conventional dip-coating method for reducing membrane infolding in the covered stent and may reduce the risk of thrombosis after its deployment.

Time-dependent topology optimization and machine learning modelling for tissue scaffolds considering bone ingrowth

Key Words: *Topology optimization, Machine learning, Scaffold, Bone ingrowth, Modelling*

Large bone defects caused by diseases, trauma and injuries remain a challenging healthcare issue. The treatment by synthetic tissue scaffolds have gained substantial attention from research and clinical communities attributable to their potential to overcome risks of infection, diseases transmission, donor site morbidity and tissue shortage associated with conventional treatments. In bone tissue engineering, the structural characteristics of scaffolds on-site play an important role in their biomechanical properties that notably affect the outcome of physical loading/mechanical stimulus regulating neo-bone formation in scaffolds. Compared to time-consuming and expensive trial-and-error experiments, computational modelling techniques have been in favour for the investigation of bone scaffolds for their compelling efficiency and strong predictive features. For bone-scaffold construct system, bone ingrowth and scaffold degradation lead to continuous variations of mechanical stimulus in a time-dependent fashion. On the one hand, such dynamic nature in bone-scaffold construct system requires for time-dependent optimization design of bone scaffolds. On the other hand, the dynamic nature renders computationally efficient issues for modelling bone ingrowth, especially for bulk scaffolds whose computational cost is prohibitive by using conventional finite element (FE) method. To address these challenging issues, we proposed a time-dependent mechanobiology-based topology optimization framework for design of bone scaffolds by considering an ongoing favourable microenvironment ensuring a long-term outcome for bone regeneration, in which a level-set based topology optimization algorithm and a time-dependent shape derivative were developed to optimize the scaffold architecture [1]. We also proposed a machine-learning (ML) based multiscale model to predict bone ingrowth outcomes in bulk scaffolds, in which the microscopic modelling was fully implemented by ML and significantly reduced the computational cost into a significantly efficient level [2]. The proposed approaches pave a new avenue for computational design and modelling of bone scaffolds, which are expected to form a promising tool for future studies by taking into the consideration of bone ingrowth outcome in scaffolds.

In this work we develop a numerical model for simulating the dynamics of millimetric droplets on inclined and non–homogeneous surfaces. Such scenarios may exhibit various regimes of different complexities such as droplet spreading, sliding and rolling. Study of droplet behaviors under different conditions attracts more and more attention due to (potential) industrial applications in microfluidic related areas. We employ *finite element method* (FEM) within *arbitrary Lagrangian–Eulerian* (ALE) framework. Under the (reasonable) assumption that there is no topology change in the droplet shape, ALE framework is a natural choice due to its ability to capture the flow dynamics and credibly track the free surface.

Stability of the numerical scheme in energy norm is (relatively) easy to satisfy on stationary meshes while it becomes non–trivial and challenging task for discretization on moving meshes. Energy stability is desirable property since it guarantees that time discretization does not introduce spurious energy into the fluid system. The main goal of this work is the development of an energy stable moving mesh strategy within ALE FEM model. The essential ingredients are the so called *space conservation law* (SCL) (see [1]) and employment of Laplace–Beltrami operator for the interface curvature evaluation (see [2]). Primary aims in designing mesh updating strategy are to keep the good quality of the mesh and to minimize the frequency of re–meshing. Considering that the droplet dynamics can simultaneously exhibit both sliding and rolling regimes, together with the energy stability requirement, such task becomes quite challenging.

Key Words: *Cardiac biomechanics, Uncertainty quantification, Cardiac disease*

Computer modelling and simulation of the beating heart must reflect on electrical activation of cells and tissue, mechanical properties of tissue, and their interaction. Electrophysiological properties of the heart have been simulated abundantly and applied to increase mechanistic understanding of disease and improve treatment development. Recent maturity in cardiac mechanical modelling increased quantitative predictive power. However, tight coupling of cardiac mechanics with the underlying electrophysiological properties of the tissue makes modelling clinical mechanical phenomena such as cardiac disease and drug effects difficult. A combination of uncertainty quantification through populations of models and fully coupled electromechanics models provide greater predictive power on cardiac mechanisms and aid treatment development for cardiac diseases.

A fully coupled electromechanics model of ventricular tissue is developed by coupling the O'Hara-Rudy[1] electrophysiology model and the Land[2] mechanics model. A population of models was created by varying 16 electrophysiological and 11 mechanical parameters at the cell level. The population was calibrated from 1000 to 187 models based on biomarkers derived from the action potential shape, calcium transient and active tension. This calibrated population was altered in 11 parameters of the cell model to represent heart failure (based on [3]). A geometry of 20x7x3 mm is simulated with 1.0 or 0.5 mm spatial resolution for mechanics or electrophysiology respectively, with free movement in the fibre direction on one side. Results are extracted at the centre of the tissue, as well as tissue shortening on the free-contracting side.

Relative to the healthy population, heart failure manifests in both electrophysiological and mechanics biomarkers. The action potential takes ~20% longer to recover from activation and peak calcium concentration in the cell is reduced by 50.9%. In a similar trend, mechanical biomarkers show 42.2% reduction in peak active force, slower contraction and more variation in recovery times across the heart failure tissue population. The peak tissue shortening in the fibre direction as a result of free contraction is reduced from 0.68±0.07mm to 0.45±0.07mm (-33.2%) and its peak is delayed by 112ms (38.6%) in heart failure.

These simulations indicate strong effects on electrophysiological and mechanical heart function by population variation and disease such as heart failure. Therefore, strongly coupled 3D models are necessary to assess the impact of biological variation, cardiac vulnerability as well as safe and effective treatment development.

Investigation of the Inertial Cavitation Threshold under a Dual-Frequency Acoustic Signal in Various Soft Tissues

Tatiana Filonets[1,2], Maxim Solovchuk[1,2*]

[1] National Taiwan University, No. 1, Sec. 4, Roosevelt Road, Taipei 10617, Taiwan, ROC, tfilonets@gmail.com

Key Words: *HIFU, Inertial Cavitation Threshold, Dual-frequency Driving Signal*

High-intensity focused ultrasound (HIFU), it's applications, and accompanying acoustic cavitation have been of great interest in biomedical engineering. HIFU therapy is a non-invasive method for tumor ablation in different organs: prostate cancer, liver, pancreas, breast, kidney, bone and soft tissue tumors [1]. One of the main mechanisms of focused ultrasound ablation is the thermal effect. However, at high ultrasound powers cavitation may appear during the treatment. Cavitation can lead to local temperature enhancement, which can be helpful during the treatment. However, it is quite difficult to control the effects of cavitation. Fundamental understanding is necessary for the further development of the technology.

At low ultrasound pressures, bubbles experience stable oscillations. When pressure reaches some critical threshold value, bubbles start to collapse. Bubble collapse is accompanied by a big increase of the local temperature and correspondingly in larger ablated volume [1]. This type of cavitation is called inertial cavitation which is investigated in the current study. We investigated the inertial cavitation threshold by analysing the dynamics of a single bubble in viscoelastic tissue.

The objective of the present study is the numerical investigation of the inertial cavitation threshold in soft tissue and its dependency on excitation parameters (single- and dual-frequency signals of HIFU), since inertial cavitation can lead to high extreme temperatures, sonoluminescence, and sonochemistry. In order to investigate the inertial cavitation threshold, acoustic wave propagation was modeled by generalized Westervelt equation [1], whereas bubble dynamics was modeled in a viscoelastic tissue by using the Gilmore-Akulichev-Zener model [2]. The inertial cavitation thresholds for different criteria, for different modes of the acoustic signal, and for different initial bubble sizes were computed. A comparison of released energy from different cavitation regimes was made. In addition, the optimal frequency combinations for a dual-frequency signal were found. The impact of different viscoelastic tissue properties and nonlinear acoustic effects on the bubble dynamics, threshold pressure, and optimal frequencies was studied.

The obtaining results demonstrated that a cavitation threshold criterion, based on a bubble size, gives lower threshold values than a criterion using bubble collapse velocity. An increase in the values of viscosity and elasticity leads to a rise in the threshold amplitude. Optimal frequency combination in dual-frequency signal mode can deliver the lowest threshold pressure that will be approximately the same for the different initial bubble sizes. Our study can provide a more detailed understanding of the inertial cavitation process and can also help to control side cavitation effects during HIFU therapy.

Mathematical modeling of ion transport through an ion channel

Kumar Saurabh[a*], and Maxim A. Solovchuk[a]

[a] National Health Research Institutes, Zhunan, Taiwan

Key Words: Ion channel flow, PNP, non-ionic interactions, ion solvation, LBM-IBM, GPU

Ion transport in the presence of fixed an free charges, in a dielectric medium can be described through Poisson-Nernst-Planck (PNP) equations. PNP equations, account for ionic interactions between ions and assume ions to be volumeless. These assumptions, however, restrict PNP equations to dilute flows. In case of flow with high ionic concentration, confined channel geometry or flows where non-ionic interactions play a significant role, PNP equations must be modified. Ion channel flow is one such system. Several extensions to PNP equations exist based on the requirement of the system. For example, Lennard-Jones model [1, 2] or Bikerman model [3, 4] can be added to PNP equations to account for the effect of non-ionic interactions. Effect of ion solvation can be included by introduction of Born solvation energy model [5, 6] or non-local electrostatics [3, 4]. Typically, in Bikerman model, transport of water molecules as a response to electrostatic and steric potential is included which is typically diffusive in nature. One can further modify these equations by including nonlinearlity and effects of viscosity of the fluid (water)for channels where, in addition to ions, water also permeates. This can be accomplished by coupling modified PNP equations with Navier-Stokes equations. Governing equations are descretized using lattice Boltzmann method. For adequate implementation of boundary conditions, immersed boundary method has been used. Further the code has been parallelized on multiple GPUs using CUDA.

Numerical Simulation of Coagulation Cascade in Aortic Dissection with Two Tears

Yan Wang[1], Kun Luo[1,*], Jianren Fan[1]

1 State Key Laboratory of Clean Energy Utilization, Zhejiang University, Hangzhou, China, zjulk@zju.edu.cn

Key Words: *Coagulation cascade, Thrombosis, Aortic dissection, Fibrin, Computational fluid dynamics*

Objectives: Type B aortic dissection (TBAD) is a major aortic catastrophe that can be acutely complicated by rapid expansion, rupture, and malperfusion syndromes. The separation of the intima from aortic walls will form a second blood-filled lumen defined as "false lumen (FL)", where the thrombus is more likely to form due to the local stasis hemodynamic conditions [1]. However, the thrombosis mechanism is still unclear and little is known about the impact of the chemical species transported by blood flow on this process. The proteins involved in the coagulation cascade (CC) may play an important role in the thrombosis process, especially in the activation and stabilization of platelets [2].
Methods: Based on the further development of the model introduced by Anand et al. [3, 4], we established a reduced-order fluid-chemical model to study the CC process in dissected aorta under realistic flow conditions. An idealized three-dimensional TBAD phantom with two tears was adopted to investigate potential thrombosis in FL and study the effect of hemodynamics on this process. The FL wall and the true lumen wall are regarded as "injury wall" and "healthy wall", respectively, and a series of boundary fluxes are set for the injury wall to describe the surface reactions occurring there.
Results: A high level of fibrin is continuously observed at the top of the FL and some time-varying areas between two tears, indicating a high likelihood of thrombus formation there. This finding is consistent with the clinical observation. The time evolution of coagulation factors is greatly affected by local hemodynamics, especially in the high disturbance zone, the evolution has characteristics of periodic changes consistent with the flow field. The ability to reproduce the CC response of the proposed model also provides a potential application to integrate with a model that can simulate platelet activities, forming a biochemical-based model which would help unveil the mechanisms of thrombosis in FL and the clinical decision of appropriate treatment.

Biomolecular Mechanics Revealed From Gaussian Accelerated Molecular Dynamics

Yinglong Miao

Center for Computational Biology and Department of Molecular Biosciences, University of Kansas, Lawrence, KS 66047, USA
Email: miao@ku.edu

Key Words: *Gaussian Accelerated Molecular Dynamics (GaMD), G-protein-coupled receptor (GPCR), Allostery, Intramembrane Proteolysis, Drug Discovery.*

Gaussian accelerated molecular dynamics (GaMD) is a robust enhanced sampling technique that works by applying a harmonic boost potential to reduce system energy barriers and accelerate biomolecular simulations by orders of magnitude[1]. Since publication in 2015, GaMD has received 350+ citations in the field. GaMD has been implemented in widely used simulation packages including AMBER, NAMD, OpenMM, GENESIS and Tinker-HP. GaMD has been also combined with compatible methods such as Replica Exchange, Umbrella Sampling, Adaptive Biasing Force and Weighted Ensemble for further improved sampling and free energy calculations. Recent developments of new Ligand GaMD (LiGaMD)[2], Peptide GaMD (Pep-GaMD)[3] and Protein-Protein Interaction GaMD (PPI-GaMD)[4] algorithms have unprecedentedly enabled microsecond atomic simulations to capture repetitive dissociation and binding of small-molecule ligands, highly flexible peptides and proteins, thereby allowing for highly efficient and accurate calculations of their binding free energies and kinetics. In addition to protein folding and conformational changes, ligand binding, protein-protein/membrane/nucleic acid/carbohydrate interactions[1], I will talk about recent applications of GaMD that have revealed dynamic mechanisms of, among others, G-protein-coupled receptor (GPCR) allostery[5] and intramembrane proteolysis by γ-secretase[6-7], and facilitated drug discovery[5].

Conformational Entropy of FG-Nucleoporins Plays the Key Role in Creating the Selective Transport Barrier in the Nuclear Pore Complex

Atsushi Matsuda[1] and Mohammad R. K. Mofrad[1,*]

[1] Molecular Cell Biomechanics Laboratory, Departments of Bioengineering and Mechanical Engineering, University of California, Berkeley, mofrad@berkeley.edu

Key Words: *Nuclear Pore Complex, FG-Nucleoporin, Intrinsically Disordered Protein*

The nuclear pore complex (NPC) is a protein complex that perforates the nuclear membrane creating the transport channel between the nucleus and the cytoplasm [1]. The NPC is composed of about 30 different proteins called nucleoporins (Nups), each of which having multiple copies in one structure. The Nups located in the central channel region are phenylalanine- and glycine-rich Nups (FG-Nups), which are intrinsically disordered and tethered on the channel wall of the NPC. FG-Nups create the selective barrier against molecular transport through the NPC; while small cargoes (less than 5-9 nm) can pass through the nuclear pore freely, large cargoes can do that only when they are bound to the nuclear transport receptors (NTRs). The selective transport is essential for the cell, but how exactly FG-Nups create such an exquisite barrier remains elusive. In our study, we hypothesized that the change in free energy associated with the conformational freedom of FG-Nups is the critical factor determining the selectivity. When a large cargo is translocating through the nuclear pore, it restricts the space available to FG-Nups decreasing their conformational entropy (and thus, increasing the free energy of the system), which virtually prevents cargo's passages. On the other hand, interactions between FG-Nups and NTRs energetically lower the free energy, allowing them to overcome the entropic barrier. To investigate our hypothesis, we computationally modelled the free energy of the system composed of FG-Nups tethered on NPC's channel [2]. We modelled FG-Nups as Gaussian chains interacting with the potential field around the surface of NTRs (that represents the adsorption to them) and calculated the free energy change while inserting a cargo into the nuclear pore. We found that the free energy change was less than thermal energy for small cargoes less than 6 nm in diameter and it was large enough for large cargoes to prevent their passage. We also found that the energetic interaction between FG-Nups and NTRs effectively lowered the free energy barrier, lowering the size limit of the transportable cargoes. This selective behaviour was affected largely by some physical parameters, such as the flexibility of FG-Nups, the length of FG-Nups, and the diameter of the nuclear pore, suggesting the possibility of the mechanical alternation of the selectivity. To further investigate our hypothesis, we simulated the dynamics of the transported cargoes through FG-Nups using a coarse-grained Brownian dynamics model. The simulation result was consistent with the free energy analysis, suggesting the importance of the conformational flexibility of FG-Nups as a key factor creating the selective barrier.

Disorder-to-order Transition in Multi-cellular Systems

Umnia Doha and M Taher A Saif*
University of Illinois at Urbana-Champaign
Urbana, Illinois, USA

Abstract submitted to the Minisymposium:
0403_ Molecular and Cellular Biomechanics_by_Hwang_Mofrad.

Living cells interact with one another, and with their extra cellular matrix. These interactions are chemical and biophysical. Interactions lead to collective behavior between cells - essential for tissue formation, morphogenesis, and tumor growth. We hypothesize that cell-cell interaction depends on the distance between them, and there exists a critical distance beyond which interaction cannot take place. We test the hypothesis by forming free-floating discs of cell-ECM mixture in vitro. We find that above a critical cell density, the discs compact and reach a specific size, independent of density. However, the rate of compaction increases with density. Below a critical cell density, the discs do not compact. High speed imaging and fluorescence microscopy reveal the underlying mechanism of this phase transition. Initially, each cell interacts with the surrounding ECM and generates a strain field, while it migrates in a Brownian motion. In contrast to the conventional view, the cell does not remodel the matrix. It does not cause any permanent deformation. The strain field is transient and reversible. At low cell density (cells are far apart), the cells do not “see” the strain field of any neighbor. They continue their Brownian dynamics without leaving any memory behind. Global symmetry is maintained without any collective behavior. The discs do not compact, independent of cell density. With increasing cell density, the cells come within their neighbors’ strain field. The probability that the two neighbors’ strain field getting aligned, both temporally and specially, increases. This breaks the global symmetry. Cells begin to interact in a feed forward way, forming a network between them, compacting the disc. The final compacted state becomes independent of the initial density. We develop a one-dimensional mathematical model of cell-cell-ECM interactions to explain the observations. The model accounts for time dependent ECM deformations mediated by the cells and their acto-myosin machinery, non-linear viscoelasticity of ECM, and the feedforward compaction process. The model captures the disorder-to-order transition as a function of cell-cell distance.

Effect of hydrostatic pressure on TRV1 conformation using molecular dynamics simulation

Key Words: *Glaucoma; Hydrostatic pressure; Mechanotransduction, Molecular Mechanics*

Glaucoma is one of the eye diseases where the retinal ganglion cells (RGCs) die, resulting in the loss of eyesight. The most common factor to cause glaucoma is an elevation of intraocular pressure (IOP). However, the mechanism that IOP causes cell death in detail remains unknown. High hydrostatic pressure applied to incubated RGCs increased Ca^{2+} concentration in cells and cell death, though they were suppressed by the antagonist of transient receptor potential vanilloid 1 (TRPV1), a membrane protein [1]. This study strongly suggests that the TRPV1 is the mechano-sensor to respond to hydrostatic pressure, open its channel, and transport Ca^{2+} through the channel. Thus, we investigated the conformation changes of TRPV1, focusing on the channel radius under the elevated hydrostatic pressure using the molecular dynamics (MD) simulation.

The PDF file of the TRPV1 structure (5IRZ) was obtained from the Protein Data Bank. Lost side chains were added with the DeepView software. The protein was embedded in 1-palmitoyl-2-oleoyl phosphatidylcholine lipids using the CHARMM-GUI-web server. The MD simulation was performed using the GROMACS software (v. 2020-3) and CHARMM27 force field. Totally 165,201 atoms of proteins, lipids, ions, and waters were generated. The simulation was performed for 100 ns in the NPT ensemble at 37°C and two pressure levels: the ordinary (12.6 mmHg) and the elevated (27.6 mmHg) pressures.

The radius of gyration at the lower gate at the elevated pressure (4.80 ± 0.08 Å) was slightly, but statistically significantly higher than that at normal pressure (4.74 ± 0.08 Å), indicating larger outwards motions of the lower gate at elevated than normal pressure. The lower gate radius at elevated pressure (0.54 ± 0.14 Å) was slightly, but statistically significantly higher than the radius at normal pressure (0.49 ± 0.14 Å), indicating an increase in the lower gate radius at elevated pressure compared to normal pressure.

These results indicate that the radius of the membrane channel TRPV1 increased under elevated pressure. However, the radius is still smaller than that of the hydrated Ca^{2+}, and we hardly conclude that hydrostatic pressure opens the channel to transport the Ca^{2+}. More extensive MD simulations are needed to provide more insight into the effect of hydrostatic pressure on TRPV1.

Key Words: *Osteocyte, Mechanosensing, Image-based simulation, Computational Biomehcanics*

Osteocytes, mechanosensory cells in bone mineralized matrix, are believed to regulate bone remodeling by sensing the flow-induced mechanical stimuli to their slender cellular processes within a canalicular space [1]. However, it is difficult to experimentally evaluate the flow and local strain of the osteocyte process membrane in vivo. In this study, to discuss the mechanosensing amplification mechanism in bone, we constructed an image-based model of osteocyte process [2], tethered to the canalicular wall, and evaluated the local strain concentration by performing fluid-structure interaction simulation [3].

A high-resolution image-based model of an osteocyte process and a canalicular space was constructed using tomographic image data obtained using ultra-high voltage electron microscopy. Tethering elements (TEs), connecting the osteocyte process membrane and the canalicular wall, were modeled as linear elastic springs and randomly arranged within the space. The lattice Boltzmann method [4] was employed for fluid flow analysis governed by the Brinkman equation, and the finite element method was used for membrane deformation analysis governed by Skalak's constitutive law [5], both of which were coupled using the immersed boundary method [6].

With the flow of interstitial fluid, local strain concentration in the osteocyte process was observed near the TEs with high tension, strongly dependent on the flow direction and the orientation angle. These results suggested that the configuration/alignment of TEs relative to the flow direction is an important factor with significant effect on the local strain concentration in osteocyte process membrane, playing an important role in osteocyte mechanosensing in bone remodeling. Further studies on the nanoscale environments of the bone canalicular space may provide a key to elucidating the mechanism of bone diseases and age-related change in bone remodeling.

This study was supported by a Grant-in-Aid for Scientific Research (A) (JP20H00659), (B) (JP19H03859), and (C) (JP19K04074) from the Japan Society for the Promotion of Science (JSPS).

ABSTRACT

Cardiovascular diseases, including myocardial infarction (MI), hypertension and atherosclerosis, are accompanied by cardiac fibrosis, which involves permanent activation of cardiac fibroblasts (CFs) during myocardial injury, resulting in excessive deposition of extracellular matrix (ECM), thereby increasing the stiffness of the pathological areas. More and more evidences showed that the matrix stiffness plays an important role in CFs activation and cardiac fibrosis, and several signal transduction factors (such as integrin, force-sensitive ion channels) that directly act on the activation of CFs have been identified. However, the key regulatory network perceiving matrix stiffness to regulate CFs activation is still unknown. Here, we detected significantly increased expressions of integrin β1 and Piezo1 in native fibrotic cardiac tissues. By using mechanically regulated in vitro cell culture models, we found that a stiff matrix induced high expressions of integrin β1 and Piezo1 in CFs, accompanied by enhanced cell activation. Importantly, we first found that a positive-feedback loop (PFL) between integrin β1 and Piezo1 enhanced cardiac fibrosis and lead to an irreversible phenotype with increasing stiffness, indicating that the PFL plays an important role in mediating substrate stiffness-induced CFs activation. Further mechanistic studies revealed that Ca2+ and YAP play important roles in integrin β1-Piezo1 positive feedback mediated fibroblast activation. Considering that this PFL is specific to CFs activation, integrin β1-Piezo1 PFL may be a fibroblast-specific therapeutic target to treat fibrotic diseases.

Mechanical response of T-cell receptors

Wonmuk Hwang

Departments of Biomedical Engineering, Materials Science & Engineering, and Physics & Astronomy
Texas A&M University, College Station, TX, U.S.A.

Key Words: Adaptive immunity, T-cell receptor, major histocompatibility complex, molecular dynamics

The αβT-cell receptor (TCRαβ) recognizes 8–10 aa antigenic peptide loaded on the major histocompatibility complex (pMHC) molecule with exquisite sensitivity, with a signal-to-noise ratio of 1 in 10^5. Yet, the equilibrium binding affinity of cognate and non-cognate pMHCs are similar and weak, on the order of micromolar range. Recent experimental findings suggest that application of physiological-level picoNewton forces to the TCRαβ-pMHC complex increases the bond lifetime in ligand-dependent manner. This suggests that TCRαβ-pMHC system exhibits catch bond behavior that mechanically enhances antigen discrimination. We address the atomistic mechanism for the activation of the catch bond by performing all-atom molecular dynamics simulation of TCRαβ-pMHC complexes under picoNewton forces and their variants. By comparing subdomain motion and dynamics of interfacial contacts, we find that the applied load suppresses certain modes of domain motion that have destabilizing effect on the TCRαβ-pMHC interface in the absence of load [1]. The dynamical activation of catch bond also allows for allosteric control of the interface by altering the motion of distal domains. The dynamical mechanism also has implications in other types of T-cell receptors.

Microtubules' Bends, Cryo-Cool Ribosomes, and Wet Proteins

Maxim Igaev[1], Lars V. Bock[1], Leonard Heinz[1], Helmut Grubmuller[1*]

[1] Max Planck Institute for Multidisciplinary Sciences, Am Fassberg 11, 37077 Göttingen,
hgrubmu@gwdg.de, https://www.mpibpc.mpg.de/de/grubmueller

Key Words: *Ribosomes, Microtubules, Atomistic Simulations, Solvent Enthalpies and Entropies*

Microtubules provide both mechanical support and, via the kinetochore, mechanical forces to the cell. The filaments can undergo growth/polymerisation and shrinking /depolymerisation phases, driven by GTP hydrolysis. Through non-equilibrium atomistic simulations of entire plus-end microtubule tips we show that the average nucleotide state of the plus-end MT tip determines the heights of energy barriers between tip conformations, such that the post-hydrolysis MT tip is exposed to higher activation energy barriers, which translates into its inability to elongate [1].

Much about the ultra-structure of microtubules ─ as well as of many other biomolecules and biomolecular complexes has been revealed by the recent resolution revolution in cryo-electron microscopy. How much of the ambient temperature ensemble of biomolecules is preserved during shock freezing prior to image acquisition is, however, an unsolved question. In shock cooling atomistic simulations of fully solvated ribosomes at realistic time scales we observed, depending on cooling rates, a marked decrease of structural heterogeneity, which we were able to quantify [2]. The observation that a kinetic two-state model improves the prediction of the decrease in heterogeneity compared to the cooling-rate independent thermodynamic model suggests that kinetic effects do contribute markedly. Small barriers between the states (<10 kJ/mol) are overcome during cooling and do not contribute to the heterogeneity of the structural ensemble obtained by cryo-EM, whereas conformational states separated by barriers above 10 kJ/mol are expected to be trapped during plunge-freezing [2]. Our results will allow one to quantify the heterogeneity of biologically relevant room-temperature ensembles from cryo-EM structures.

In these processes, as well as quite generally in protein folding and the thermodynamics of biomolecular stability, the solvent shell plays a pivotal role as, e.g., the effect of cold denaturation clearly demonstrates. We will present a new method to compute solvent enthalpies and entropies with spatial resolution and thus to quantify the underlying thermodynamic enthalpy/entropy tug-of-war [3]. For the example protein crambin, we quantified the local effects on the solvent free-energy difference at each amino acid and identified strong dependencies of the local enthalpy and entropy on the protein curvature. Remarkably, more than half of the solvent entropy contribution arises from induced water correlations [3].

The Gating Mechanism of the Mechanosensitive Ion Channel NompC

Chen Song

Peking University, 5 Yiheyuan Road, Beijing, China, E-mail: c.song@pku.edu.cn

Key Words: Mechanosensitive Ion Channel, NompC, Molecular Dynamics, Gating, Ankyrin Repeat

Mechanosensitive ion channels are membrane proteins that can respond to mechanical stimuli to open and conduct ions across cell membranes to trigger downstream signaling. NompC is a crucial mechanosensitive ion channel for the sensation of touch and balance in *Drosophila melanogaster*, representing an ideal model for the study of the tethered mechanosensitive ion channels. Based on the Cryo-EM structure of NompC, we performed molecular dynamics simulations to reveal the atomistic details of the channel gating mechanism. Our results showed that a pushing force from the intracellular region can open the channel, but not a pulling force. The supercoiled ankyrin repeat region acts like a spring with a force constant of $\sim$13 pN/nm, which can transfer forces at a rate of $\sim$1.8 nm/ps to the linker helix domain. A subsequent rotation of the TRP domain, which is next to the linker helix domain, was found to be related to the opening of the channel, and the key residues forming hydrogen bonds along the force convey path were identified. We propose that the push-to-open gating mechanism may enable cells to feel external compression or volume shrinkage, and we speculate that a force transformation from pushing to twisting might be the key to the channel gating.

Key Words: *Cardiac perfusion, Multiphysics Problems, Myocardial blood flow*

Myocardial perfusion is the delivery of blood to the heart muscle, supplied by the coronary circulation. Reduced coronary flow rate, due for example to atherosclerosis, can lead to ischemic cardiopathy and, possibly, to an infarct of the myocardium.

We present a mathematical and numerical model for human cardiac perfusion which accounts for the different length scales of the vessels in the coronary tree. Precisely, a clear scale separation can be noticed between the coronaries laying on the epicardium and the smaller vessels penetrating into the tissue [1]. We adopt a multi-physics approach in which the epicardial vessels are represented with a three-dimensional fluid-dynamics description (Navier-Stokes) whereas the intramural vessels are modeled by means of a multi-compartment porous medium (Darcy's law) [2]. These two models are coupled using interface conditions based on the continuity of mass and momentum. Since the heart is composed by regions perfused by distinct epicardial vessels [3], we partition the myocardial domain in perfusion regions. A suitable calibration procedure is introduced to use patient-specific values for the parameters of the model.

The multi-physics approach was used to reproduce myocardial blood flow (MBF) maps in nine patients (four healthy and five with detected coronary artery disease), showing an excellent agreement between the computed MBF and MBF measured from clinical data [4]. The results of this work proved the accuracy and the reliability of the proposed multi-physics model in reproducing MBF. In this way, we could provide a quantification of the MBF avoiding in principle invasive MBF measurements such as using stress CT. This could be useful for the assessment of the coronary artery disease and for guiding revascularization decisions.

Studying the heart using computational models has gained wide attention over the last decade. A large focus area has been the improvement of coupled electromechanical models and their efficient numerical treatment. Electromechanical models, including biophysically detailed mechanisms for excitation-contraction coupling, mechano-chemical, and mechano-electrical feedback, are important candidates to investigate, for example, the mechanisms underlying arrhythmias in diseased hearts. However, these investigations require simulations of full cardiac cycles at the organ-level, which, despite advances over the last years, remain very expensive from a computational standpoint. In order to improve the performance of fully coupled electromechanical simulations we present a novel, general, space-time adaptive framework using the finite element method and an adaptive Godunov-type operator splitting. Since the required element size and time step length for the electrical subproblem are an order of magnitude smaller than for the mechanical subproblem, we nest the mesh for solving the electrical problem into the mesh for solving the mechanical problem. Further, we utilize adaptive refinement of the electrical mesh to drastically reduce the total computational cost during depolarization, while being able to capture the electrical wavefront with high accuracy. Additional speed-up is gained by using a novel time-adaptive operator splitting scheme [1], where the time steps of the electrical problem are nested into the time step of the mechanical problem, which remains constant. The presented framework also utilizes an augmentation of the local adaptive time stepping by Qu and Garfinkel [2]. Verification and work-precision studies are carried out and a study on a realistic biventricular rabbit model with measured microstructure [3] is presented, suggesting a speed-up of more than an order of magnitude while preserving high accuracy.

Dynamic Fracture of Skin and Subcutaneous Tissue During Auto-injection

Vivek D Sree, Arezoo Ardekani, Pavlos Vlachos, and Adrian B Tepole

Purdue University, West-Lafayette, IN, US

Key Words: *Dynamic fracture, Nonlinear finite elements, Soft Tissue Mechanics*

Delivery of life-saving drugs through injection to the subcutaneous space has increased rapidly, in part due to the introduction of auto-injector devices [2]. Auto-injectors are a convenient method for self-administering a medication. In an auto-injector, a syringe containing drug is accelerated by a pre-compressed spring which drives the needle into the skin and keeps the device pressed into the skin during the drug injection process. In contrast to manual injection, speeds during auto-injection can be up to 1-10m/s. Additionally, while there have been various efforts characterizing the fracture of skin and subcutaneous tissue at constant speeds [2], auto-injectors are characterized by complex dynamics which have only recently been studied in detail [3].

Here we present a computational model of auto-injection biomechanics. We capture fracture initiation, propagation, and frictional contact between fracture surfaces and needle with a cohesive zone model. A 3D model and an equivalent pair of 2D plane-strain models are presented. Skin and subcutaneous tissues are modelled as hyper-viscoelastic. To calibrate the model, data from experiments on constant needle insertion from the literature are reproduced using a combinatorial optimizer. Inferred elastic and fracture parameters from the optimization are further compared to values reported in the literature, independently of the needle insertion data. With a validated model, we fully couple the dynamic fracture model to a validated nonlinear model of an auto-injector [3]. The coupling is done through a user material subroutine in the finite element package Abaqus that calls the auto-injector model and passes the reaction force at the needle as input; it then retrieves the kinematics of the needle and enforces them in the finite element simulation.

The computational model is used to conduct a comprehensive parametric study in which both material properties and auto-injector parameters are varied. A crucial finding from this parametric study is that pre-compression by a base-plate imparts strain energy to the system, some of which is used in crack formation, reducing the force for injection. This observation in the model aligns with previous experimental work at constant needle speeds [2]. Finally, a comprehensive sensitivity analysis is carried out after replacing the expensive finite element model with an efficient yet accurate Gaussian process surrogate. This analysis is the basis for future design iterations that can robustly produce desired injection dynamics under uncertainty.

Soft biological tissues are characterized by different cell types and extracellular matrix constituents. Structural proteins, such as collagen and elastin, are the most important ones among the extracellular components from a mechanical point of view. Collagen fibers exhibits a wide orientation distribution with the function of micromechanical reinforcement for the tissue. A striking characteristic of living soft tissues is their tendency to maintain a preferred non-stress-free mechanical state, namely mechanical homeostasis [1]. Growth and remodeling, which refer to change in mass and internal structure in living soft tissues, are crucial mechanobiological processes in developing healthy tissue and in several pathological conditions. Growth and remodeling, driven by biomechanical stimuli deviating the system from its homeostatic state, are essential to restoring mechanical homeostasis. Therefore, developing models that account for growth and remodeling is crucial to increase the insight into connections between biology and mechanics and understand the evolution of diseases.
The present work aims to develop a statistics-based approach to describe growth and remodeling in soft tissues with wide orientation distribution of fibers. Starting from the homogenized constrained mixture theory [2-3] and using the concept of mechanical homeostasis [1], we propose a probabilistic description of the fiber-mass evolution law. This description accounts for a statistical distribution of collagen fibers [4], assuming that new fibers are deposited according to a specific statistical law. We demonstrate that our framework can reproduce growth and remodeling behavior as observed in soft tissues with a statistical distribution of fiber orientations under uniaxial and biaxial loading [5].

Mixed-dimensional Modeling of Stented Arteries using Geometrically Exact Beam Theory

Nora Hagmeyer[1*], Ivo Steinbrecher[2], Matthias Mayr[3] and Alexander Popp[4]

[1] University of the Bundeswehr Munich, Werner Heisenberg-Weg 39, 85577 Neubiberg, Germany
e-mail: {nora.hagmeyer, ivo.steinbrecher, matthias.mayr, alexander.popp}@unibw.de, web page: https://www.unibw.de/imcs-en

Key Words: *stented artery, geometrically exact beam theory, mixed-dimensional modeling*

Cardiovascular diseases represent one of the leading causes of death worldwide. This motivates the desire for minimally invasive procedures, reducing the risk of operative complications during arterial and coronary repairs, and accounts for the success of treatment procedures such as balloon angioplasty for stenotic arteries. Nevertheless, the occurrence of post-operative complications such as leakage, migration, restenosis, etc. frequently necessitates follow-up surgeries. The reasons for these complications are not fully understood yet. This motivates computational simulations as a tool to enhance the understanding of the underlying causes.

Computational simulation of such biomedical problems are rather complex and necessitate large system sizes to adequately capture important phenomena. Motivated by the research of Tambača et al., who utilized the benefits of 1-dimensional beam theory to efficiently simulate the behavior of coronary stents and observed a good agreement with full-dimensional models at a fraction of the system size [1], we follow the concept of modeling stents using geometrically exact beam theory. It becomes clear that not only the behavior of the stent but especially global effects of its interaction with the arterial wall and the flow around it is of interest.

This talk will demonstrate the use of highly efficient 1-dimensional stent models based on geometrically exact beam theory with a special focus on the stent's interaction with 3-dimensional continuum equations via mixed-dimensional modeling approaches as proposed in [2, 3].

Key Words: *microscale cardiac mechanics, intracellular and extracellular mechanics, cardiomyocyte contraction, cell-based geometries*

Cardiac tissue primarily consists of interconnected cardiac cells which contract in a synchronized manner as the heart beats. Most computational models of cardiac tissue, however, homogenize out the individual cells and their surroundings. This approach has been immensely useful for describing cardiac mechanics on an overall level, but gives very limited understanding of the interaction between individual cells and their intermediate surroundings. Several models have been developed for single cells, see e.g. [1, 2]. In this work, we extend the mechanical part of these frameworks to a domain representing multiple cells, allowing us to investigate cell-matrix and cell-cell interactions. We present a mechanical model in which each cell and the extracellular matrix have an explicit geometrical representation, similar to the electrophysiological model presented in [3]. The strain energy functions are defined separately for each of the intracellular and extracellular subdomains, while we assume continuity of displacement and stresses along the membrane. Active tension is only assigned to the intracellular subdomain. For each state, we find an equilibrium solution using the finite element method. We explore passive and active mechanics for a single cell surrounded by an extracellular matrix and for small collections of cells combined into tissue blocks. The explicit geometric representation gives rise to highly varying strain and stress patterns. We show that the extracellular matrix stiffness highly influences the cardiomyocyte stresses during contraction. Through large-scale simulations enabled by high-performance computing, we also demonstrate that our model can be scaled to small collections of cells, resembling small cardiac tissue samples.

Simulation of Biological Networks: Phase-field Modeling of Slime Molds

Christian Peco[1*], Farshad Ghanbari[12] and Francesco Costanzo[13]

Slime molds develop macroscopic pulsating networks able to modify their structure in response to the environment. Despite their relative simplicity and the lack of a neural system, these organisms can move, solve mazes, sense nutritious or toxic agents at a distance, and even memorize periodic events. Recent studies have revealed that slime mold's pulsating unit — at the small scale — relies more heavily than previously thought on the feedback between the mechanical properties of the membrane, cytoplasm and chemical kinetics. However, the capacity to understand and replicate the emergent behavior at the level of the whole organism remains a challenge. We establish here a theoretical and computational framework to explain, quantify and reproduce how this feedback between macroscopic features and local tuning of mechanical properties determines an emergent coordinated response of the network morphology. These networks have the ability to grow, survive, or die in the presence of different concentrations of nutrients, and to redistribute them thus optimizing its proliferation. We propose a phase-field scalar variable to represent the network matrix evolution, and a diffusive-advective process for the nutrient distribution. This framework enables high fidelity simulations of slime molds in the three-dimensional space, which are challenging due to the coupled physics involved, high-order partial differential equations, and the existence of a highly complex evolving geometry. We support our simulations with experiments on a particular slime mold (*Physarum polycephalum*). The emergent properties of these organisms are similar in nature to tissues with transport networks, and can play a central role in wound healing, metastasis formation, or embryology. This investigation is a road to the microstructural design of active soft matter, object of interest in many fields of engineering and science.

Steklov-Poincaré analysis of the basic three-domain stent problem

Irving Martinez[1*], **Alessandro Veneziani**[1]

[1] Emory University, 400 Dowman Drive, Atlanta, Georgia, United States 30322,
irving.martinez@emory.edu

Key Words: *Stents, Computational Fluid Dynamics, Multi-domain Simulations, Interface Mechanics, Domain Decomposition*

The Steklov-Poincaré problem was previously considered in the artery lumen and wall setting with a single interface. Here the analysis is expanded to incorporate solute behavior in the presence of a fixed-volume, solid, simple stent. In this geometry, a third domain is added to the two-domain structure of wall and artery. Through this intersecting domain volume setting there are three interfaces: lumen-wall, stent-lumen, and wall-stent.
Steady-state incompressible Navier-Stokes equations are used to explain the behavior of blood through the lumen, while advection-diffusion dynamics are considered for the solute mechanics across the lumen, wall, and stent. Having a fixed blood velocity value, Steklov-Poincaré decomposition of the advection-diffusion equations is applied locally to each of the interfaces. To unify these instances on a global scale, their overall intersection is explored in a smaller manifold, reducing the problem to one previously solved by Quarteroni, Veneziani, and Zunino. [1]
Through finite element analysis (FEM), the solution is discretized and found to be convergent. Finally, computational simulations of one, three, and five stent rings of different thickness, placed between straight and curved volumes of inner and outer cylindrical meshes, were performed using NGSolve, confirming the convergence of the solution and its relation to the coarseness of the mesh.

A Multi-resolution MPS-FEM Coupling Method and Its Application to flapping flight Simulation

Zumei Zheng*

School of Mechanical Engineering, Qilu University of Technology (Shandong Academy of Sciences), No.3501, Daxue Road,Changqing District, Jinan 250353, Shandong, P R China, zhengzumei10@qlu.edu.cn

Key Words: *Multi-resolution, Moving Particle Simulation Method, Finite Element Method, Fluid Structure Interaction*

In this work, a MPS-FEM coupling method is developed for the simulation of fluid-structure interaction problem, where the multi-resolution moving particle simulation (MPS) method is developed for the fluid flows and the finite element method (FEM) is employed to account for structural deformation. By using the multi-resolution MPS method, the fluid area is divided into sub-domains with different particle spacing, and an average effective radius is applied to assure the accuracy and stability. Besides, a modification is made for the kernel function to guarantee the interaction force calculation between interface particles. Then the developed multi-resolution MPS method is coupled with the FEM for fluid structure interaction simulation, where the interface force is calculated by using a volume function. By using the volume function, interaction between structures and fluid particles with different particle spacing can be solved easily, and there is no matching requirement between particle spacing and finite element size. Numerical examples are simulated to verify the effectiveness of the multi-resolution MPS method and the coupling scheme. Finally, the developed MPS-FEM coupling method will be used for the simulation of flapping flight.

Advances in Computational Biomechanics of Insect-inspired Flapping Flights

Hao Liu [1*]

[1] Graduate School of Engineering, Chiba University, 263-8522, hliu@faculty.chiba-u.jp (and URL, if available)

Key Words: *Insect-inspired flight system, flapping aerodynamics, flight stability and control, passive and active mechanism*

Flying insects power and control their flight by flapping their wings. By controlling their aerodynamic forces and torques, they can precise and agile aerial manoeuvres. From an engineer's perspective, their closed-loop, the flight control system depends on an overarching external mechanical 'frame' consisting of wings and thoracic shell, which is actuated by an internal system consisting of flight muscles and a complex nervous system [1]. Insect flights are diverse but robust relying on the integration of different flexible structures including wings, exoskeletal elements, wing-hinges, musculoskeletal elements, and sensors. In this talk I will highlight the recent advances in computational modelling of biomechanics in insect-inspired flapping flight systems with a focus on how they can offer a powerful and feasible tool to unravel a passive and active mechanism (PAM) strategy, i.e., how these flexible structures work interactively and complementarily to achieve a systematically efficient and robust flapping-wing dynamics and aerodynamics as well as flight control in various natural environments.

Aerodynamics and Energetics in Hawkmoth Forward Flight

Yujing Xue[1,2*], Xuefei Cai[1,2] and Hao Liu[1,2]

[1] Shanghai Jiao Tong University, Shanghai 200240, People's Republic of China

Key Words: *Computational fluid dynamics, Unsteady aerodynamics, Energetics, Forward flight*

While hovering flight has been the main subject associated with flapping-wing aerodynamics, considering staying a particular point in space is very rare for most flying insects, unsteady aerodynamics and energetics associated with forward flight remain poorly understood yet. Here we address a computational fluid dynamic (CFD)-based study of flapping aerodynamics and energetics in hawkmoth forward flight over a broad range of flight velocity. We build up a wing-body morphological model of hawkmoth *Manduca Sexta* and mimic the realistic wing-body kinematics based on experimental data which enables trimmed forward flights in various forward flight velocities based on a genetic algorithm embedded with a CFD-driven aerodynamic model. Flapping forward flights are simulated with a high-fidelity CFD solver, capable of achieving precise prediction of complex vortical dynamics, both cycle-averaged and transient aerodynamic force, torque and power with a variety of flying motions and wing-body kinematics. Through the visualization of near- and far-field vortical structures, we examine the leading-edge vortex (LEV)-based mechanisms and wake topologies as well as their correlations with aerodynamic force production in various flight speeds. While the intense LEVs owing to flapping wings are responsible for creating most of the aerodynamic force, the body-based vortex induced by wing-body interaction is verified capable of augmenting the vertical force production up to 10% of the insect weight at fast velocities. The aerodynamics and energetics are further investigated in a broad parameter space in terms of aspect ratio, wing-to-body mass ratio and reduced frequency. The time-averaged body-mass-specific mechanical power exhibits a *J*-curve with increasing flight velocity, with a low level of power-consumption at most velocities but relatively high costs in hovering and the top velocity. The realistic wing-to-body mass ratio points to an obvious inflection in the power curve and high-*AR* wings can enhance the LEV production with the spanwise wing morphology matching its formation. Our results thus provide an overall understanding of the aerodynamics and energetics in various forward flights of hawkmoth, which may provide a potential design guideline for biomimetic flapping micro aerial vehicles.

Key Words: Fluid-structure interaction, Flapping wings, Acoustic simulations

Fluid-structure-acoustic interaction problems are becoming more popular with the recent development of computational technologies. This numerical study focuses on developing efficient fluid-structure acoustic interaction solvers to examine birds flights. In particular, we will investigate the noise in flipping wings and experiment with some noise mitigation techniques that birds use. The work present in this paper is mainly about the development and validation of numerical methodologies. Capturing sound waves in a numerical simulation is challenging, as the length scale of sound waves is significantly smaller than that of aerodynamic fluctuations of macro variables. Thus, selecting an appropriate methodology is critical in aeroacoustic simulations. To improve the efficiency of the solving process, the lattice Boltzmann method (LBM), which describes the evolution of mesoscale velocity distribution functions, based on free-streaming and collision is used. LBM is intrinsically suitable for acoustic simulations, due to the simple nature of the solution process, large spatial resolutions and efficiency with parallel simulations. There are many different versions of LBM with distinct collision operations. The recursive and regularized (RR) BGK collision operator, which was developed based on higher-order Hermit polynomials was used to improve the numerical stability. For computations, a truncated domain is generally used. The perfectly matched boundary condition was employed at the outer domain, avoiding the nonphysical sound wave reflections. To model the fluid-solid interface of fluid-structure interaction problems, the widely used immersed boundary method was used. The von Neumann analysis was conducted investigating the stability of the regularised LBM. It was found that the accuracy and stability of the regularised LBM were improved, when the collision operator was computed from the Hermite polynomials up to 4^{th} order instead of the 2^{nd} order. In addition, two benchmark cases: the propagation of an acoustic monopole and point source and the sound generated by a stationary cylinder in a uniform flow were conducted, as validation studies. Predictions given by the IB-regularised LBM showed a good agreement with numerical simulations and analytical solutions reported in previous publications, demonstrating the capability of the IB-regularised LBM presented in this study for acoustic problems. Using the methods presented here, we will investigate the duty of separated wing-tips in noise mitigation of bird's flights in future.

Computational analysis of fluid-structure interaction in case of dragonfly flying in the vortex street

Ying Wang[1, 2], Wei Shyy[1] and Huihe Qiu[1*]

[1] Department of Mechanical and Aerospace Engineering, The Hong Kong University of Science and Technology, Hong Kong Special Administrative Region of China
[2] School of Energy and Power Engineering, University of Shanghai for Science and Technology, Shanghai, China
(Corresponding author: meqiu@ust.hk)

Key Words: *Dragonfly, Fluid-structure interaction, Wing kinematics, Cylinder*

The fluid-structure interaction (FSI) in case of a live-sized dragonfly staying in the vortex street is investigated by numerical simulations. The vortex street is generated by a circular cylinder. A dragonfly model is placed on the downstream centerline of the bluff cylinder at various distances away from the center of the cylinder with considering effects of wing phase difference and wing pitching. The overset grid technology is adopted to simulate the dragonfly flapping motion. The Navier-Stokes equation in the arbitrary Lagrangian-Eulerian form is solved by coupling with the kinematics equation. Cases including stationary position with and without wing deformation are investigated. These results numerically found that, under proper conditions, the vortices can help raise the thrust force or vertical force without expending any energy of its own. This observation is also significant in the development of low-drag energy harvesting devices, and in the energetics of dragonfly clinging on long and thin pond vegetation.

Effect of Inclination Angle of Origami Winged Seeds on the Terminal Velocity and Rotation Period

Key Words: *biomimetic, winged seed, biological fluid mechanics, terminal velocity, auto-rotation, origami technology, numerical simulation*

Bioinspired designs that imitate animals and plants' movements, behaviors, characteristics, appearance, or structure have attracted much attention due to their unique properties and potential applications to micro aerial vehicles. Examples include birds or insects, which can generate thrust and lift through flapping-wing systems [1]; wind-dispersed seeds and fruits with lightweight and flight organs such as wings that can extend the flight time and range [2]. In addition, when the Reynolds number is low, this type of flight mechanism can improve the shortcomings of current fixed-wing aircraft and may be used in topographic surveys, disaster relief operations, and military activities.

The flight mechanism of winged seeds only requires simple geometrical changes, unlike insects or birds, requiring neuromuscular control for driving [3] to reduce its descent speed. In this paper, inspired by the Dipterocarpaceae winged seeds, we use our newly-invented three-winged origami paper seeds as a model system to study the falling speed and rotation period of such bioinspired devices. We use origami winged seeds because their wing shape and angle can be readily changed to understand how they affect the flight. We changed the three-winged model's wing inclination angle, measured with respect to the horizontal plane, between 30-50 degrees. We found that when the inclination angle is smaller, the paper seeds tend to rotate at high speed and have a longer falling time in the free-fall experiment. This result is consistent with our numerical simulation. In addition, we found that the angle of the paper seeds oscillated periodically during the falling process from the simulation result. We also designed and assembled a vertical wind tunnel so that the three-winged model can fly in a specific range within the tunnel, facilitating the observation of the relationship between wing vibration, rotation period, and terminal velocity during flight.

Key Words: *Lift, Wake, Vorticity Centroid, Flapping Flight, Unsteady Aerodynamics*

The Kutta-Joukowski (KJ) theorem is usually used to estimate the lift from the wake in experimental measurements of free-flight animals. However, the KJ theorem may lead to puzzling results when it is applied to estimating the lift from the unsteady wakes [1]. We investigate this problem by using three prevalent flapping rectangular wing models [2], where the unsteady wakes are obtained by numerically solving the Navier-Stokes equations at low Reynolds numbers. The evolution of the wake and the unsteady lift generated by the flapping wing models are analysed in details. The limitations in applying the KJ theorem to flapping wings are quantitatively examined by using a simplified lift model for unsteady viscous flows [3]. It is found that neither the unsteady nor the time-averaged lift coefficient is correctly predicted when the parameters for the KJ theorem are selected according to the widely accepted ways in the literature.

We propose a vorticity-centroid wake width model based on the vortex impulse theory to improve the prediction to the lift. The proposed model computes the effective span width based on the vorticity centroid width of the wake, in which the evolutionary effects of the complex vortex structures in the wake is taken into account. When the vorticity-centroid wake width is used, the KJ theorem gives a good prediction to the time-averaged lift. Furthermore, we investigate the phase difference of unsteady lift caused by the quasi-steady assumption of the application of the KJ theorem to the flapping flight and quantitatively link the phase difference to the local fluid acceleration. We show the phase difference can be corrected by using an added mass lift model. The proposed model can be used to estimate the lift from the velocity and vorticity on a Trefftz plane in the wake. This work is helpful to clarify the error in estimating the lift of flapping flight.

Key Words: Flapping wing, Fluid–structure interaction, Two-way coupling, One-way coupling, Mars

In Mars exploration, rovers often suffered from rugged areas such as cliffs and dunes, which are operationally hazardous and could be very challenging to investigate. The success of the first small helicopter, Ingenuity, by NASA has a significant impact for its demonstration that the device with rotary wings could fly in a low-Reynolds-number regime on Mars [1]. However, we consider a flapping-wing micro air vehicle (FWMAV) promising on Mars because the flapping flight is efficient in the low-Reynolds-number regime, at least on the Earth, as birds and insects take advantage of various unsteady mechanisms to achieve flight [2]. The biggest challenge for its development is an appropriate understanding of a flapping flight with flexible wings, which is significantly complicated because flexible flapping wings can undergo large-scale deformations due to the effects of wing inertia and the aerodynamic forces exerted by the surrounding atmosphere. Fluid–structure interaction (FSI) analysis is a powerful tool for accurate investigations, but it usually has a very high computational cost, making it challenging to perform necessary parametric studies for practical designing. An efficient FSI analysis method is required. On Mars, whose atmospheric density is around 1% that of Earth, aerodynamic forces have a relatively small influence on wing deformation and may even be negligible in some cases. We thus investigate the relative contributions of the inertial force of a flapping wing and the aerodynamic forces exerted by the surrounding Martian atmosphere using a two-way coupled FSI simulation [3], and identify the conditions under which the aerodynamic forces are negligible. Then, we develop a computationally efficient one-way coupled FSI analysis system based on the interface-capturing method to design a flexible flapping wing for Mars exploration [4]. Under the obtained conditions, we perform parametric studies on flexible flapping wings in the Martian environment with multiple aerodynamic parameters, various kinematic parameters, and material properties of the wing. We conclude that an FWMAV with a payload of around 5 g can fly for more than 1 minute for the maximum density of the Martian atmosphere.

Key Words: *Insect Flapping Flight*, *Fluid-Structure Interaction (FSI) Design*, *Insect-Inspiration*, *2.5-Dimensional Structure*, *Computational Biomimetics*, *Passive Mechanism*, *Flapping Motion*, *Feathering Motion*, *Design Window (DW)*, *Micromachining*, *Nano Air Vehicle (NAV)*

A flight device for insect-inspired nano air vehicles (NAVs) can use the fluid-structure interaction (FSI) to create the characteristic motions of flexible flapping wings. This design concept or the FSI design will be essential for further miniaturization of NAVs, since it will reduce the mechanical and electrical complexities of the flight device.

In this study, an insect-inspired flapping wing with a 2.5-dimensional (2.5-D) structure is proposed using a computational approach for the FSI design [1], which consists of the direct numerical modelling of the strongly coupled FSI, the dynamic similarity framework, and the design window (DW) search. The proposed wing uses the passive mechanisms of both the flapping and the feathering mimicking actual insects. This wing can be fabricated using micromachining techniques based on the photolithography because of the 2.5-D structure.

The proposed wing consists of the flexible wing membrane, the leading-edge beam, and the plate spring at the base connected to a micro actuator. The membrane and spring lead to the FSI-cause of the feathering motion [2] and the resonance in the flapping motion, respectively. These motions are strongly coupled with each other. Hence, the direct numerical modelling of the strongly coupled FSI is essential in the performance evaluation of each design solution.

The flapping frequency and the lift force are taken as the design parameter and the objective function, respectively. An existing area of satisfactory design solutions or the DW [3] is searched such that each design solution in the DW can generate a sufficient lift force. In our future work, the manufacturable solutions will be selected from the DW, and they will be fabricated using the micromachining technique.

Key Words: *Butterfly, Unsteady Aerodynamics, Flight Dynamics, Fluid Structure Interaction*

Insects are impressive creatures due in part to their small size and agile flight maneuvers [1]. Additionally, butterflies can be highly efficient fliers, as evidenced by monarchs having the longest migration amongst insects [2]. To begin uncovering the complex mechanisms enabling monarchs to migrate roughly 80 million times their average body length, high-fidelity modeling tools must be developed. These tools must consider the distinguishing features of monarchs – their low flapping frequency, high Reynolds number (amongst insects), large wings relative to their body, low wing loading, flexibility of their wings, and the highly coupled interplay between the instantaneous wing aerodynamics and dynamic body response.

Many high-fidelity models have been used for the study of butterfly flight to date [3–5]. However, most have neglected the passive wing pitching arising from butterfly's flexible wings. Here, we propose a framework that tightly couples the effects of all three physics solvers using a dynamic relaxation scheme. As such, the highly nonlinear interplay between fluid, body, and passive wing dynamics is efficiently accounted for in each time step. We apply the model to the free flight of monarch butterflies, resulting in stable motion for many periods without any controller. Analysis of the vortex dynamics resulting from the unsteady aerodynamics coupled to the large rotations and undulations of the body will be presented.

Key Words: *Insect Flapping Flight, Fluid-Structure Interaction, Pixel Wing Model, Passive Mechanism, Inertial Effect, Aerodynamic Effect, Cambering*

Characteristic deformations are observed in many species of insects. Especially, cambering in the flapping wings plays an important role in increasing their aerodynamic efficiency [1]. Mimicking the cambering in insect-like flapping wing nano air vehicles (FWNAVs) will increase their flight performance. It seems that the cambering is caused by the aerodynamic and wing's inertial forces (passive cambering) because of the lack of interior muscles in insect's wings. It is important to determine the relative importance of their forces in the passive cambering, which will provide an insight for the further development of insect-like FWNAVs.

Hence, in this study, the relative importance of the aerodynamic and wing's inertial forces in the passive cambering is determined using the fluid-structure interaction (FSI) analysis framework for insect's flapping wings. This framework consists of (1) a pixel wing model, which consists of a structured mesh using shell finite elements [2], and can simulate the passive cambering as well as the passive feathering, (2) a projection method [3, 4], which splits the simultaneous equation system for the FSI into two equilibrium equations and a pressure Poisson equation, and (3) the FSI nondimensional parameters [5], which can measure the dynamic similarity between the model flight and the actual insect flight.

It is shown from a numerical example using the flight data of small insects that the aerodynamic force is the basis of the passive cambering, and the wing's inertial force enhances it. In our future work, this understanding will be used in the design of insect-like FWNAVs.

S-Version of Finite Element Method Using B-Spline Basis Function for FSI Analysis

Nozomi Magome[1*], **Naoto Mitsume**[2]

[1] College of Engineering Systems, School of Science and Engineering, University of Tsukuba, 1-1-1 Tennodai, Tsukuba, Ibaraki, Japan, magome.nozomi.sw@alumni.tsukuba.ac.jp
[2] Faculty of Engineering, Information and Systems, University of Tsukuba, 1-1-1 Tennodai, Tsukuba, Ibaraki, Japan, mitsume@kz.tsukuba.ac.jp

Key Words: *s-version of FEM, B-spline, fluid–structure interaction, flapping flight*

A considerable number of recent studies have been conducted on a numerical simulations for flapping-wing flight of a bird and an insect as a fluid–structure interaction (FSI) phenomenon. Numerical methods to deal with moving boundaries in FSI analysis can be categorized into tracking and capturing methods. However, the tracking method may generate distorted mesh for fluid domain, which makes the calculation unstable, because the flapping motion is associated with a large deformation, movement, and contact of boundaries. On the other hand, the capturing method can not maintain high-resolution boundary layer meshes for the moving boundary layers, resulting in low accuracy.
To overcome these challenges, we have extended s-version of FEM (SFEM) [1] to FSI analysis. SFEM has been studied mainly in the field of structural mechanics. In addition, we propose a new method to achieve both robustness of fluid meshes for moving boundaries and high resolution in a local domain. In this framework, we apply structured meshes based on interface capturing method to the entire domain. Higher resolution arbitrary Lagrangian–Eulerian (ALE) meshes based on interface tracking method are superimposed on the boundary layers and the surrounding area which require high spatial resolution. In addition to conventional Gauss quadrature, SFEM requires Gauss quadrature for partly superimposed finite elements with different basis functions. In SFEM, it is well known that using Lagrange polynomials as the basis functions leads to discontinuous integrand which reduces the accuracy. To solve this problem, many studies have been conducted to improve the integral accuracy by decomposing integral domains [2], but all of them are computationally expensive. In this study, we use 2nd-order B-spline function as a basis function of the structured mesh in order to make the integrand continuous and improve the integral accuracy while reducing computational cost. Numerical benchmark tests using manufactured solutions are presented to validate the numerical accuracy. Finally, the proposed method is applied to the coupled problem of flapping-wing flight.

The effects of wing kinematics on both normal forward flight and escape flight of a dragonfly [1] are numerically investigated. A Navier-Stokes-based numerical model has been adopted and results substantiated by experimental data [2]. To shed light on the interplay between kinematics and aerodynamics, a parametric study of the kinematics has been conducted. It is found that in escape flight the dragonfly can generate additional lift while redistributing some of the thrust as well however to the expense of overall efficiency that drops by 13%. Compared to the normal forward flight, the escape mode produces larger force peaks along with higher wing loading and corresponding to more pronounced wing deformation. In escape flight wing-wing vortex interactions and downwash effects increase lift as result of mostly the changes in flapping positional angle. Regarding the phasing of the wings, in comparison with the force change caused by angle of attack variation, the influence of the phasing between fore- and hind-wing in escape flight is secondary. On the other hand, the change of angle of attack played a major role in facilitating the aerodynamic performance of normal forward flight by affecting the formation and orientation of the wing bound vortexes and directing momentum. With appropriate combination of phase and angle of attack of fore- and hind-wings, the relative magnitudes between the thrust and the lift vary. The results can help develop flight control strategies for micro scale air vehicle design.

Key Words: *Abdominal Pelvic Cavity Muscles, Stress Urinary Incontinence, Muscle Strength*

Stress urinary incontinence (SUI), i.e., "the complaint of involuntary loss of urine on effort or physical exertion or sneezing or coughing" is prevalent in adult women. Pelvic floor muscle (PFM) strength components have been positively associated with continence (1). Stronger abdominal muscles contraction is associated with higher Intra-abdominal pressure (2). From a biomechanical perspective, woman with stronger abdominal muscles would need stronger PFM to maintain continence.

PFM strength (cmH_2O) and PFM endurance (s) were assessed by manometry. Peak torque of trunk flexor muscles (Nm), Maximal Expiratory Pressure and Maximal Inspiratory Pressure (cmH_2O) were used as a surrogate measure of superficial abdominals, deep abdominals, and the respiratory diaphragm strength, respectively.

The sample comprised 48 healthy women aged 19 to 49 years with normal Body mass index. Thirty-four were continent and 14 had SUI symptoms. The majority were nulliparous (n=42; 87.5%) and reported regular physical exercise/sport practice (n=35; 72.9%). No differences were found between continent and incontinent women in the reported variables ($p>0.05$). Regarding PFM function variables, there was no statistically significant differences in maximal strength between continent and incontinent: 62.7 cmH_2O (95% CI: 53.8 - 71.6) versus 62.6 cmH_2O (95% CI: 45.3 -80.0) p=0.725, strength: 51.9 cmH_2O (95% CI: 44.7 - 59.0) versus 55.0 cmH_2O (95% CI: 40.5 -69.5) p=0.964, and endurance 52.9 s (95% CI: 36.0 - 69.8) versus 57.2 s (95% CI: 23.7 - 90.6) p=0.812, respectively. Differences were found in abdominal cavity muscles strength between continent and incontinent: superficial abdominals 105.9 Nm (95% CI: 96.4 - 115.4) versus 128.5 Nm (95% CI: 115.7 - 141.2) p=0.005, deep abdominals 62.9 cmH_2O (95% CI: 55.6 - 70.2) versus 76.2 cmH_2O (95% CI: 65.0 - 86.4) p=0.028, and Diaphragm 61.4 cmH_2O (95% CI: 53.8 -69.0) versus 73.4 cmH_2O (95% CI: 64.1 - 82.7) p=0.048.

In this sample, no differences were found in PFM strength components between groups. Women with SUI had stronger abdominal cavity muscles strength than continents.
Should PFM strength components be considered in relation to abdominal muscles strength when evaluating women with SUI?

Key Words: *Vaginal Delivery, Uncoordinated Uterine Activity, Excessively Short Resting Stage, Tachysystole, Numerical Simulation, Finite Element Method*

During a normal vaginal delivery, the muscle cells propagate electrical signals throughout the uterine wall, which will result in a synchronized set of uterine contractions and resting stages [1]. An uncoordinate uterine activity may change the uterine contractions pattern and impact fetal and maternal health [2]. There are many uterine activity abnormalities identified by the specialists, such as precipitate labor, excessive frequency of contractions (tachysystole), excessive contraction duration, excessively short resting intervals, among others.

The main goal of this work is to investigate the maximum principal stress distribution and the collagen fibers stretch in the uterine tissue during a vaginal delivery with (i) a normal contraction pattern, (ii) excessively short resting intervals and (iii) excessively uterine high frequency (tachysystole).

A biomechanical model comprising a fetus and a uterus was developed and an electro-chemo-mechanical constitutive model that triggers uterine contractions was implemented and validated with literature findings. The normal contraction pattern was defined with a contraction time of 80s and a resting time of 60s, while for the excessively short resting interval the contraction time was maintained, and the resting stage was shortened to 20s. Finally, the tachysystole was characterized by a contraction time of 55s and a resting stage of 35s.

Generally, the excessively short resting intervals exhibit higher average maximum principal stresses during the contraction and resting stages, lower average fibers stretch values in the longitudinal direction, and higher stretch in the circumferential direction. This indicates that more intense uterine contractions will be created, which my interfere with the fetal oxygenation, since higher contractions tend to compress the uterine vessels. On the other side, the tachysystole exhibit generally lower stress values during the uterine contraction and higher stress values during the resting stages, higher stretch in the longitudinal direction and lower stretch in the circumferential direction. Once more, oxygenation deficiency may be detected, since the uterine muscle does not have time enough to rest, leading to higher stresses at the end of each resting interval.

Key Words: *Childbirth biomechanics, Finite element model, Pelvic floor dysfunctions, Fetal positions*

Childbirth can be a mechanically traumatic event. The impact of the fetal position on women and neonates is considerable, with high rates of birth trauma associated with occipito-posterior (OP) positions [1]. The main goal of this study is to analyze the influence of a persistent OP malposition on the maternal pelvis and pelvic floor, with the mother assuming a flexible-sacrum birthing position.

A finite element model was used to simulate vaginal delivery in the vertex presentation. The mother's model includes the pelvic floor muscles (PFM), hip bones, sacrum, coccyx, and main pelvic ligaments [2, 3]. The movement of the coccyx around the sacrococcygeal joint is allowed, to mimic maternal positions in which the weight of the body is off the sacrum. The fetus is composed of the skin, skull, brain, sutures, and fontanelles [4]. Two simulations were performed in Abaqus® software to mimic the fetus in occipito-anterior (OA) and OP positions. To evaluate the effect of distinct fetal positions, the stretch, maximum principal stresses, and coccyx rotation were analyzed.

The maximum principal stresses were measured at different paths of the PFM and were higher for the OP position. The major difference was an increase of 55.20% in the OP position compared to the OA. The coccyx rotation in the OA and OP positions was, respectively, 0.98º and 2.17º. The fetus has more difficulty progressing in the OP position since the maximum muscles' stretch is achieved at a later stage.

Childbirth is a complex biomechanical process that can put both mother and fetus at risk of injuries. The maximum principal stresses obtained indicate that the muscles are subjected to higher stresses in the OP position at the instant of maximum stretch. These results demonstrate that the OP is more demanding for the PFM, corroborated by previous numerical and clinical studies [5]. Furthermore, in the OP position the coccyx needs to rotate twice as much as the OA position for the fetus to progress. In clinical terms, the OP position appears to be more demanding for the mother's pelvis. To conclude, the current work demonstrates that the OP position can be harmful to the pelvic floor muscles during a flexible-sacrum maternal position.

Improving Childbirth Outcomes: A Biomechanical Approach

Dulce Oliveira[1*], Teresa Mascarenhas[2]

[1] INEGI, LAETA, Porto, Portugal, doliveira@inegi.up.pt
[2] CHUSJ, FMUP, Porto, Portugal, tqc@sapo.pt

Key Words: *Occiputanterior position, Occiputposterior position, Childbirth-related injuries, Numerical simulations*

Despite being a natural physiological event, childbirth is a very complex process that can have a negative impact on women. Childbirth-related trauma impacts millions of women and babies worldwide [1]. Pelvic floor muscle injury, both micro and macrotrauma, has an incidence of 10-36%, and anal sphincter injury of 4-6.6% [2]. Pelvic floor injuries are exacerbated by fetal malposition, such as persistent occiputposterior (OP) position, which is estimated to affect 1.8-12.9% of pregnancies [3]. Childbirth-related trauma plays an important role in the development of pelvic floor dysfunction, and diagnosis rates at the time of injury are still poor [4].

The biomechanical aspects of childbirth are still not entirely understood; as such, computer models aim to improve current knowledge by evaluating mechanical aspects during vaginal delivery, such as stress, strain, forces and contact pressures. A 3D biocomputational model previously developed to simulate vaginal deliveries was used in our studies, including the mother and the fetus [5]. The birthing process is a complex physiological phenomenon, so it is important to have a representative anatomical model to perform accurate biomechanical simulations. From our studies, we realized that the OP position induces a greater increase of the anteroposterior diameter. Furthermore, the maximum value occurs at a higher location in the birth canal compared to the normal position (occiputanterior, OA). This need for longer stretches at an earlier time of fetal descent can be a reason for prolonged second stage of labor in case of fetal malposition. The OP position is more demanding for the pelvic floor muscles than the OA position, corroborated by clinical studies [5]. On the other hand, the OP position was considered biomechanically favorable to the fetus since it suffers less head deformations. The molding index, which evaluates the variation of predefined diameters of the fetal head, shows significantly lower values for the OP position compared to the OA position.

Key Words: *Finite Element Methods, Pelvic Cavity, Pelvic Organ Prolapse, Surgical Implants, Anchoring Technique*

The uterosacral (USLs) and cardinal ligaments (CLs) are the primary pelvic structures that provide apical support to the upper vagina and uterus [1]. The impairment of these connective tissues is strongly associated with pelvic organ prolapse (POP), namely the uterine prolapse, that has long been studied [2]. The prevalence of POP, which is now up to 41.1%, is likely to increase due to improvements in overall healthcare and increase life expectancy [3].The synthetic implants are used for the reconstructive surgery of POP, but severe complications associated with their use have been reported, mainly related to their mechanical properties.

In this study, we mimicked a transvaginal reconstructive surgery to repair/replace the apical ligaments (USLs) and CLs), by modeling, after their impairment and/or total rupture, respectively. The implants to reinforce/replace these ligaments were built based on literature specifications and their mechanical properties were obtained through uniaxial tensile tests. Additionally, the effect of mesh anchoring technique (simple stitch and continuous stitch) was analyzed.

The absence/presence of the synthetic implant was simulated when total rupture of the CLs and USLs occurs, causing a variation of the vaginal displacement (9% for the CLs and 27% for the USLs). The simulations also showed that there was a variation of the supero-inferior displacement of the vaginal wall between different anchoring techniques, being approximately of 10% for the simulation USLs and CLs implant.

The simulation was able to mimic the biomechanical behavior of the USLs and CLs, in response to different anchoring techniques, which can be help improving the outcomes of the prolapse surgery in the future.

Key Words: *Neuron intracellular transport, Traffic jam, Microtubule swirls, PDE-constrained optimization, Isogeometric analysis*

The intracellular transport process plays an important role in delivering essential materials throughout branched geometries of neurons for their survival and function. Many neurodegenerative diseases have been associated with the disruption of transport. Therefore, it is essential to study how neurons control the transport process to localize materials to necessary locations. Here, we develop a novel optimization model to simulate the traffic regulation mechanism of material transport in 3D complex geometries of neurons. The transport is controlled to avoid traffic jam of materials by minimizing a pre-defined objective function. The optimization subjects to a set of partial differential equation (PDE) constraints that describe the material transport process based on a macroscopic molecular-motor-assisted transport model of intracellular particles. The proposed PDE-constrained optimization model is solved in complex tree structures by using isogeometric analysis (IGA). Different simulation parameters are used to introduce traffic jams and study how neurons handle the transport issue. Specifically, we successfully model and explain the traffic jam caused by reduced number of microtubules (MTs) and MT swirls. In summary, our model effectively simulates the material transport process in healthy neurons and also explains the formation of a traffic jam in abnormal neurons. Our results demonstrate that both geometry and MT structure play important roles in achieving an optimal transport process in neuron.

Key Words: Multiscale modeling, Pulmonary airflow simulation, Respiratory system, Mixture theory

In this study, a 3D-1D-0D multiscale method is developed for simulating pulmonary airflow. Airflow in the respiratory bronchioles and alveoli were calculated by a two-phase mixture model (0D) coupled with the lung deformation. The terminal bronchioles were approximated by a pipe model (1D) which is connected with the 0D lung parenchyma. Such strong coupled 0D-1D system is solved by finite element method. For the airflow inside the trachea and bronchus, a three dimensional (3D) computational fluid dynamics analysis was performed by finite volume method based on the real bronchial geometry extracted from CT images (3D). The multi-scale respiratory simulation system was realized by satisfying the mass and momentum conservation law. In addition, the continuous condition of pressure was also ensured at the terminal nodes of the 1D airways and the corresponding mesh central points of 0D mixture solid. The coupling between 3D bronchus and 1D terminal bronchioles is conducted by transferring the information of the flow rate and pressure between the 3D bronchial terminal's outlets and the connected 1D bronchioles inlets. Such data transfer is performed by a serial staggered fashion. Therefore, the overall 3D-1D-0D coupling algorithm belongs to the class of two-way weakly coupling type. The results showed the same changed lung volume with the volume of inhalation flow, which demonstrated the mass conservation condition. Moreover, to consider the effect of airway deformation on the airflow patterns, we extracted the displacements of airway wall from the elements of surrounding lung parenchyma. A dynamic mesh method was then employed to describe the temporal and spatial nodal displacements of the whole 3D airway domain. The results indicate that the airway deformation has an apparent influence on the airflow structure in the respiratory system.

PDE-preserved learning architecture for predicting spatiotemporal dynamics based on differentiable programming

Jian-xun Wang*, Xinyang Liu, Han Gao and Pan Du

Aerospace and Mechanical Engineering, University of Notre Dame, 46556, IN, US

Key Words: *Geometric deep learning, differentiable programming, Surrogate modeling*

The recent development of physics-informed deep learning (PiDL) that leverages domain knowledge and physical prior has shown promise in solving physical problems in many science and engineering fields. In most existing PiDL works (e.g., physics-informed network, or PINN), physics prior knowledge is mainly utilized to inform or constrain the training process of the network by incorporating known governing equations into the loss function in a soft manner. However, the mathematical understanding of the system has not been fully leveraged, for example, in network architecture design. In this work, we develop a novel physics-informed deep learning architecture for predicting spatiotemporal dynamics. The network construction, layer connections, and output constraints are based on the discretized structure of the governing partial differential equations (PDEs). The learned model can be used as a parametric surrogate model for the fast prediction of spatiotemporal dynamics, facilitating UQ analysis in high-dimensional complex systems. We will demonstrate the proposed method on cardiovascular biomechanics, where the geometries of the problems are complex and irregular. In particular a statistical generative model for 3-D patient-specific shapes will be constructed based on a handful of available baseline patient geometries. An unsupervised shape correspondence solution is used to enable geometric morphing and a compact geometric design space can then be constructed by the statistical generative shape model. With the fast surrogate model, we demonstrate its application in shape optimization and UQ analysis in a massively scalable manner.

Physics-Informed Data-Driven Parameter Identification of Human Musculo-Skeletal Systems

Karan Taneja[1*], Xiaolong He[1], Jiun-Shyan Chen[1] and Qizhi He[2]

[1] University of California San Diego, 9500 Gilman Dr, La Jolla, CA 92093, USA,
[2] University of Minnesota-Twin Cities, Minneapolis, MN 55455, USA

Key Words: *Physics-informed neural networks, parameter identification, human musculo-skeletal motion*

The motion of human musculo-skeletal (MSK) systems result from a complex interaction of the neural signals that activate the muscles leading to forces produced by the length and velocity changes from the contraction of muscle tendon units. These forces produce torques at the joints (joint kinetics), updating the joint angles and velocities (joint kinematics) resulting in the controlled movement of the human MSK system. In practise, for analysing the motion of a specific subject, the muscle activation can be estimated by using surface electromyography (EMG) signals whereas the muscle tendon force generating properties can be obtained by using parameterised hill-type models. These parameters are identified by solving an optimization problem with given motion capture data, in which the algorithms for calibration can be computationally expensive. In this work, a physics-informed data-driven framework for parameter identification of human MSK systems is proposed, where neural networks enhanced with physics-based constraints are employed. Specifically, residuals of governing differential equations are penalized in the loss function for a more robust system identification procedure satisfying the underlying physics, such as both joint kinetics and joint kinematics. The proposed framework is examined by identifying parameters in muscle models given subject specific EMG and motion data, where the identified parameters of the subject are then compared against physiological estimates. Future work to enhance the framework using continuum level muscle-tendon behaviours as well as medical imaging data is also highlighted.

Shear Induced Cell Damage: Multiscale Modelling and Experimental Validation

Meghdad Razizadeh[1], Mehdi Nikfar[1], Ratul Paul[1], and Yaling Liu[1 2]

[1] Department of Mechanical Engineering and Mechanics, Lehigh University
[2] Department of Bioengineering, Lehigh University

Key Words: *Multiscale Modelling, Coarse Grained Molecular Dynamics, Cell Squeezing*

Shear stress in medical devices such as ventricular assist devices and microfluidic devices can be significantly higher than physiological range, leading to damage of cells. Under these high shear stresses, cells experience sublytic damage, which is temporary pore forms allowing cellular content to release or outside agent to delivery in, or in more critical cases, complete rupture and apoptosis of cell. Cell damage can cause serious problems like anemia, arrhythmias, stroke for hemolysis of red blood cells, or immune response for white blood cells. However, transient cell damage is also widely used for intracellular delivery of drugs and agents into cells, yet the underlying mechanics is not well understood. We developed a cellular model of cell damage through multiscale modelling and experimental characterization. This a bottom-up cellular model, in contrast with the present continuum approaches, is not device-dependent, thus can predict cell damage and agent delivery in any device. At the continuum scale, computational fluid dynamics (CFD) simulations are used to get the shear stress history of individual cells passing. Mesoscale fluid-structure interaction simulations is performed to determine the critical threshold of pore formation and geometrical characteristics of pores under various loading conditions. Coarse-grained molecular dynamics (CGMD) simulations of pore formation in a membrane patch that explicitly includes both lipid bilayer and cytoskeleton particles are used to develop the subcellular damage model. The critical strain and dynamic process of pore formation under physiologically strain/shear rates are quantified. The cell damage and intracellular delivery are found to be a function of shear stress and exposure time. Finally, the cell damage during squeezing through microfluid channels of various widths and length was studied experimentally. The simulated cell damage agrees well with experimental results.

A Fully Coupled Thermo-Hyperelastic Constitutive Model of Myocardium: The Role of Thermoelastic Anisotropic Conduction and Cellular Death During Radiofrequency Catheter Ablation

Leonardo Molinari[1*], Luca Gerardo-Giorda[2], Alessio Gizzi[3]

Key Words: Constitutive model, Myocardium anisotropy, Radiofrequency catheter ablation, Cellular death dynamics, Multiphysics couplings, Finite Element Analysis

Radiofrequency catheter ablation (RFCA) is an effective treatment for various types of cardiac arrhythmias [1]. However, constitutive models of RFCA lack a reliable three-dimensional microstructural representation of the tissue. In the present work, we propose a novel transverse isotropic thermo-hyperelastic constitutive model of the myocardium fully coupled to the thermo-electrical problem arising from the RF procedure. We account for the local anisotropy in the thermo-electrical conduction mechanisms and employ a three-state cell death model including mechanical damage. We implemented a two-way coupling between the mechanical and heat transfer model at the constitutive level through the multiplicative decomposition of the deformation gradient. A thermoelastic equation for the heat transfer model, consistent with generalized thermodynamics-based constitutive theories [2], is further advanced. We numerically solved the multiphysics problem within an idealized tissue domain, adopting a mixed finite element scheme augmented by a constant power constraint for the RFA procedure. Remarkable results include: (i) the elliptically-shaped thermal lesions; (ii) stiffening of the tissue; (iii) a residual tensional state due to damage accumulation. These results offer compelling evidence for enhanced predicting capabilities of RFCA numerical models, including microstructural features of the tissue and multiphysics coupling with the clinical procedure. We discuss future developments, including viscous dissipation and generalized remodel theories, as well as an extensive clinical validation that is foreseen to confirm the application of our approach to device design and therapeutic optimization.

Key Words: *Adherens junction, computational model, cadherin, actin, cell adhesion*

Adherens junctions (AJs) are protein complexes at the cell-cell interface that withstand mechanical forces and maintain tissue structure. They also regulate intracellular signalling for cell growth, division and death. Proper adherens junction structure and function is therefore critical for tissue development. Adherens junction dysfunction causes cancer metastasis. Deciphering the molecular regulators of adherens junctions is challenging partly because of complex interactions between mechanical forces and chemical signals within the junction. Unravelling the interactions would help identify potent targets for cancer therapies and also help advance technologies like bioprinting and regenerative medicine.

AJs involve extracellular bindings between cadherin molecules and intracellular interactions between cadherins and the actin cytoskeleton. Both cadherin and actomyosin cytoskeletal dynamics are reciprocally regulated by mechanical and chemical signals, which subsequently determine the strength of cell-cell adhesions and the emergent organization and stiffness of the tissues they form. However, an understanding of the integrated system is lacking.

We present a new mechanistic computational model of intercellular junction maturation in a cell doublet to investigate the mechano-chemical crosstalk that regulates AJ formation and homeostasis. The model couples a 2D lattice-based model of cadherin dynamics with a continuum, reaction-diffusion model of the reorganizing actomyosin network through its regulation by Rho signaling at the intercellular junction. We demonstrate that local immobilization of cadherin induces cluster formation in a cis less dependent manner. We then recapitulate the process of cell-cell contact formation. Our model suggests that cortical tension applied on the contact rim can explain the ring distribution of cadherin and F-actin on the cell-cell contact of the cell-doublet. Furthermore, we propose and test the hypothesis that cadherin and F-actin interact like a positive feedback loop, which is necessary for formation of the ring structure. Different patterns of cadherin distribution were observed as an emergent property of disturbances of this positive feedback loop. We discuss these findings in light of available experimental observations on underlying mechanisms related to cadherin/F actin binding and the mechanical environment.

Key Words: Poroelasticity, Multiphysics Problems, Biomedical Applications

In this talk we propose a novel coupled poroelasticity-diffusion model for the formation of extracellular oedema and infectious myocarditis valid in large deformations, manifested as an interaction between interstitial flow and the immune-driven dynamics between leukocytes and pathogens. The governing partial differential equations are formulated in terms of skeleton displacement, fluid pressure, Lagrangian porosity, and the concentrations of pathogens and leukocytes. A similar model with applications in morphogenesis is also discussed.

A five-field mixed-primal finite element scheme is proposed for the numerical approximation of the problem, and we provide the stability analysis for a simplified system emanating from linearisation. We also discuss the construction of an adequate, Schur complement based, nested preconditioner. Numerical tests exemplify the properties of the new model and of the mixed schemes.

Key Words: *PtdInsP3, Dictyostelium, Stochastic Simulations, Membrane Curvature, Diffusion, Plasma Membrane, Pattern Formation*

PtdInsP3 lipid signalling is essential for regulative processes in *Dictyostelium* and mammalian cells. Recently, it has been experimentally shown that waves of PtdInsP3 are solely self-regulated through the mechanical deformation of the plasma membrane even in the absence of the regulative actin network. The dynamics are defined by the underlying excitability and the shape of the membrane, leading to horizontal and vertical, as well as transient spot dynamics of PtdInsP3 domains[1]. Further, it was shown that the diffusion of t hose domains are strongly influenced by strongly curved membranes, as it is observed at the leading edge of protrusions and macropinocytic cups[2].

In order to fully understand the experimental observations, we investigate the thermo-mechanical effects of the PtdInsP3 lipid signalling *in-silico* with realistically shaped three-dimensional plasma membranes, as observed *in-vitro*[1], an experimentally based reaction-diffusion scheme [1, 3] and the stochastic τ-leap method to simulate the PtdInsP3 domain dynamics [4]. We found that the variation of membrane deformation, excitability and curvature dependent diffusion regulates the PtdInsP3 lipid signalling, and can recover fundamental system dynamics as observed in experiments.

Key Words: *Deep neural network, Blood flow modeling, Reduce-order modeling*

One-dimensional blood flow modeling has proven to be a powerful tool to capture flow and pressure waveforms in complex vascular networks. Despite its computational efficiency, the existing developments are still far from achieving real-time, especially in large vascular networks, and keeping in mind the large number of time steps required to model a single cardiac cycle. Additionally, one-dimensional models typically rely on the use of 0 D lumped parameter models to capture the effect of the truncated vasculature at each of the model outlets. This turns into dozens of parameters to be estimated at the patient-specific level. Overall, this still results in computationally intensive simulation pipelines, incompatible with the stringent clinical time frame.

In the last years, a wealth of techniques have been proposed to accelerate computational physics simulations via machine learning. These techniques fall into two large groups. From one side, non-intrusive reduced-order modeling techniques, which typically use a (sufficiently) large dataset of simulations to extract, via proper orthogonal decomposition, intrinsic similarities of the solutions and project them into a lower-dimensional space. Then, machine learning (neural networks, Gaussian process regression) is used to find the nonlinear relationship between model parameters and the solution on the reduced space. On the other side, physics-informed machine learning is based on building a neural network architecture aimed to replace the computational physics model via enforcing the satisfaction of the driving physical laws. More recently, techniques that combine the two approaches have also been proposed.

Whereas these techniques are very promising, their relative advantages and disadvantages remain unclear. This work aims at comparing different machine learning-based reduced-order modeling, physics informed machine learning, and hybrid methods for accelerating one-dimensional blood flow simulations. The methods will be compared in terms of accuracy of the predicted solution, the satisfaction of the underlying physical laws, required offline training time, and computational speed-up in the on-line evaluation. To do so, a set of models based on idealized and patient-specific geometries will be used to extract relevant conclusions.

Key Words: *Computational fluid dynamics, Isogeometric analysis, Moyamoya, MRI, Wall shear rate score*

Background and Purpose. Moyamoya disease (MMD) is a progressive steno-occlusive cerebrovascular disease leading to recurrent stroke. There is a lack of reliable biomarkers to identify unilateral stroke MMD patients who are likely to progress to bilateral disease and experience subsequent contralateral stroke(s). We hypothesized that local hemodynamics are predictive of future stroke and set out to noninvasively assess this stroke risk in pediatric MMD patients.

Methods. MR and X-ray angiography imaging were utilized to reconstruct patient-specific models of the circle of Willis of 6 pediatric MMD patients who had previous strokes, along with a control subject. Blood flow simulations were performed by using a Navier-Stokes solver within an isogeometric analysis framework. Vascular regions with a wall shear rate (WSR) above the coagulation limit ($> 5000\ s^{-1}$) were identified to have a higher probability of thrombus formation, potentially leading to ischemic stroke(s). Two metrics, namely, "critical WSR coverage" and "WSR score", were derived to assess contralateral stroke risk and compared with clinical follow-up data.

Results. In two patients that suffered a contralateral stroke within two months of the primary stroke, critical WSR coverages exceeding 50% of vessel surface and WSR scores greater than 6x the control were present in multiple contralateral vessels. These metrics were not as conclusive in two additional patients with 3-to-5-year gaps between primary and contralateral strokes. However, a longitudinal study of one of these two cases, where a subsequent timepoint was analyzed, accurately predicted disease stabilization on the primary stroke side and an elevated contralateral stroke risk, thus indicating that post-stroke follow-up at regular intervals might be warranted for secondary stroke prevention.

Conclusions. WSR-based metrics could be predictive of future stroke risk after an initial stroke in MMD patients. In addition, more accurate predictions may be possible by performing patient-specific hemodynamic analysis at multiple timepoints during patient follow-up to monitor changes in the WSR-based metrics

Data-driven reduced order models for cardiovascular simulations

Luca Pegolotti[1,3*], Natalia L. Rubio[2], Martin R. Pfaller[1,3], Eric Darve[2,3], and Alison L. Marsden[1,2,3,4]

[1] Stanford University, Department of Pediatrics (Cardiology), Stanford, CA, USA
[2] Stanford University, Department of Mechanical Engineering, Stanford, CA, USA
[3] Stanford University, Institute for Computational and Mathematical Engineering, Stanford, CA, USA
[4] Stanford University, Department of Bioengineering, Stanford, CA, USA

Key Words: Reduced-order models, neural networks, cardiovascular simulations

We are interested in learning reduced-order models for cardiovascular applications from high-fidelity 3D simulations. We are motivated by the fact that traditional physics based reduced-order models—e.g., 0D and 1D models—can suffer from loss of accuracy in complex geometries (featuring, for instance, many bifurcations and/or pathological conditions such as stenoses) [1]. We first consider a combined domain-decomposition and Proper Orthogonal Decomposition (POD) approach; here, the target geometry is approximated by simple geometrical building blocks equipped with a low number of basis functions for velocity and pressure. In [2], we show that this approach is accurate in approximating velocity, pressure and wall-shear stress, and leads to significant speedup (at least 10 times) with respect to the Finite Element Method (FEM). We also consider a machine learning method trained on a large dataset of high-fidelity simulations available in the Cardiovascular Biomechanics Computational Lab at Stanford University, the Vascular Model Repository (VMR). We develop a surrogate 1D solver based on graph neural networks (GNNs) by following a strategy similar to that presented in [3]. In each timestep of our method, the GNN encodes, processes and decodes the flowrate and pressure values located at the nodes on the centerline of the cardiovascular model and outputs the updated state of the system. We will present comparisons with standard 1D reduced-order and high-fidelity simulations and highlight the strengths and challenges of our approach.

Key Words: Reduced Order Model, Computational Fluid Dynamics; Data-driven Modeling

Coronary artery disease is characterized by a narrowing or stenosis in the vessel. Fractional flow reserve (FFR), a measure of stenosis severity, is the pressure gradient across a stenosis and is measured by an invasive and technically challenging procedure. Developing a computational method to estimate FFR avoids risks associated with this procedure; however high-fidelity (3D) models are computationally expensive and impractical for real-time diagnosis. Low fidelity models based on 1D nonlinear theory are computationally inexpensive[1], but cannot fully characterize the complexities of the flow across a stenosis. In this project, we aim to develop a reduced order model (ROM) capable of accurately describing the complexities of flow across a coronary stenosis.

An ensemble of precomputed solutions can be represented on a graph, where each node is a separate boundary value problem. This allows the use of nonlocal calculus to calculate the terms for a library of candidate operators[2]. The terms we choose to include in the candidate library are based on techniques such as polynomial expansion of the quantities of interest. We also include terms based on existing models of the pressure gradient across a stenosis[3]. Terms from this library are eliminated through stepwise regression until the loss reaches a Pareto front. The new model is identified as the most parsimonious one on the Pareto front.

To validate this approach, we started with a problem with a known analytical solution, laminar flow through a pipe. We successfully recovered the known model for the pressure gradient, i.e., Poiseuille flow. The methods presented are a preliminary proof of concept for generating a reduced order model using a graph theoretic approach. These methods will be used for models of increasing geometric complexity, from a tapered pipe, to an idealized stenosis, to a more realistic stenosis with curvature.

Effect of Non-sinus-matching Bioprosthetic Aortic Valve Design on Coronary Flow

Mehdi Saraeian[1*], Ming-Chen Hsu[2] and Adarsh Krishnamurthy[3]

[1] Iowa State University, Ames, IA 50011, USA, mehdi@iastate.edu
[2] Iowa State University, Ames, IA 50011, USA, jmchsu@iastate.edu

Key Words: Sinus-matching, Bioprosthetic valve, Fluid structure interaction, Parametric modeling

Technological advances in medical imaging and computer simulations have made it possible for us to better understand the cardiovascular system. Even though there are several morphologies of the aortic cusps in the native anatomy of a healthy heart, the leaflets always match the sinuses of Valsalva. Recent studies have shown that the mechanism of aortic leaflet closure is correlated with the formation of the vortices in the sinus of Valsalva. These vortices allow the cusps to open and close while exerting a fluid dynamic control mechanism that positions the cusps away from the aorta wall, and the slightest reversed flow in the ascending aorta will close the valve [1]. Bioprosthetic aortic valve interventions change the hemodynamic behaviors of the heart and the formation of these vortices. While there have been efforts to design asymmetric frames to better match the aortic annulus, the effect of sinus-matching leaflet design has not been investigated. In this work, we present a comprehensive framework for designing axially asymmetric/symmetric stented prosthetic aortic valves and aortic roots using parametric geometry and Fluid-Structure Interaction (FSI) analysis [2, 3]. We investigate the effects of a sinus-matching leaflet design in an axially asymmetric aortic valve configuration and compare it to the conventional axially symmetric leaflet design. We look at the orifice and coaptation areas quantitatively and the vortex formations qualitatively. This framework can be ultimately used to design optimal bioprosthetic aortic valves that match the sinus geometry for a given patient, leading to better hemodynamic performance of the left cardiac system.

Geometric deep learning and statistical shape modeling for fast surrogate CFD simulations of patient-specific hemodynamics

Pan Du, Han Gao, Xiaozhi Zhu, and Jian-xun Wang

Aerospace and Mechanical Engineering, University of Notre Dame, 46556, IN, US

Key Words: *Patient-specific CFD, surrogate modelling, machine learning, UQ*

Optimization and uncertainty quantification (UQ) have been receiving an increasing amount of attention in computational hemodynamics. However, existing methods based on principled modeling and classic numerical techniques have faced significant challenges, particularly when it comes to complex 3D patient-specific shapes in the real world. First, it is notoriously difficult to parameterize the input space of arbitrarily complex 3-D geometries. Second, the process often involves massive forward simulations, which are extremely computationally demanding or even infeasible. We propose a novel deep learning solution to address these challenges and enable scalable geometric UQ and optimization. Specifically, a statistical generative model for 3-D patient-specific shapes will be constructed based on a handful of available baseline patient geometries. An unsupervised shape correspondence solution is used to enable geometric morphing and a compact geometric design space can then be constructed by the statistical generative shape model. In order to build a fast forward map between geometric input space to the solution space of functional information, we propose a supervised deep learning solution. With the fast surrogate model, we ran test cases to demonstrate its application in shape optimization and UQ analysis in a massively scalable manner.

Identifying the Biomechanical Properties of a Flexible Thrombus

James N. Hewett[1*] **and Mathieu Sellier**[2]

[1] University of Canterbury, Christchurch 8140, New Zealand, james@hewett.nz
[2] University of Canterbury, Christchurch 8140, New Zealand, mathieu.sellier@canterbury.ac.nz

Key Words: Thrombosis, Inverse Problems, Phase Field Model, Computational Fluid Dynamics

Modelling thrombosis with numerical simulations remains as a challenging task [1] consisting of multi-physics, multiscale, and complex fluid dynamics with fluid-structure interactions. In this work, we focus on the problem of identifying the mechanical properties of developed thrombi within blood vessels, using the dynamics of the interface between blood flow and thrombi.

A viscoelastic porous medium was assumed for the thrombus because of its fibrous network. The fluid-structure interaction between the thrombus and blood flow was modelled in the Eulerian reference frame using the Cahn-Hilliard and Navier–Stokes equations [2]. Two biomechanical properties of the thrombus, specifically the permeability and viscoelastic modulus, was identified with an inverse model using a twin experiment approach. Synthetic results were first generated with a prescribed permeability and viscoelastic modulus, and then second an optimiser was employed for minimising the difference between the simulated and synthetic thrombus interface. Such a method of parameter identification has previously been used elsewhere, including for describing temperature-dependent lava rheology [3].

We discuss the sensitivity of biomechanical properties to the thrombus dynamics, and the robustness of the inverse method by adding noisy data to imitate experimental uncertainties. Finally, we compare our results with recent work using physics-informed neural networks [4].

Key Words: echocardiography, machine learning, image-to-analysis, image segmentation, SimVascular

Despite numerous advances in diagnosis and treatment, cardiac disease (CD) remains the leading cause of death in the United States. Prevention and early diagnosis of CD often requires monitoring of the heart itself. Monitoring is typically accomplished through echocardiographic (i.e., cardiac ultrasound) screening due to its accessibility, cost-effectiveness, real-time capabilities, and demonstrated prognostic value.

Identifying and evaluating biomarkers for CD depends on efficient segmentation and analysis of echocardiographic images. Processing these images can be time-consuming, expensive, and error-prone due to reliance on expert human technologists and radiologists. Automation of MR and CT image processing using deep learning has shown significant promise, but processing of volumetric ultrasound data has lagged behind other modalities due to its lower signal-to-noise ratios, lower image contrast, bone and gas image artifacts, and organ boundary uncertainty. For example, open-source image-to-analysis toolkits like SimVascular can automatically process cardiac MR and CT images [2], but this functionality is not supported for echocardiographic data [3].

In this talk, we will present ongoing work in our comprehensive investigation of automatic segmentation methods for 3D and 4D echocardiographic images [1]. We will show how these echo segmentations can serve as patient and mouse-specific geometry in blood-vascular and blood-heart simulations in SimVascular. Then, we will present novel regional geometric and biofluidic biomarkers of cardiomyopathy obtained from mouse and human data sets.

Key Words: Fluid Structure Interaction, Discrete Element Method, Biomedical Applications

Fluid-particle interaction phenomena in complex domains are prevalent in many physiological and biomedical applications. One important application concerns the transport of emboli in a large artery, where the complexity of embolic particle dynamics and their interaction with complex pulsatile flow structure inside large arteries renders significant challenges in predicting the transport of such particles. This problem is particularly important for arterial embolisms, where knowledge of embolus transport to major blood vessels helps in diagnosis and treatment planning for stroke and other major cardiovascular diseases. Despite several existing approaches to handle two-way coupled fluid-particle interaction, simultaneous coupling for a multi-particle system in a complex physiological flow domain remains a challenge. In this work, an implementation of a coupled fluid-particle interaction algorithm for a complex multi-particle system is presented. The two-way coupled fluid-particle interaction is resolved using an immersed finite element method in which the particle domain is represented as a Lagrangian mesh moving on top of a fixed Eulerian fluid mesh [1, 2]. This allows for the fluid mesh to be generated independently from the solid structure, thereby simplifying the meshing process for multi-particle systems. The no-slip condition and interaction force at the fluid-particle interface is enforced using a mesh-to-mesh interpolation via finite element basis function transformation. Support size on which the fluid-structure interaction force is applied is commensurate with size of elements touching the particle domain and therefore optimal in an element-wise sense. Each immersed inertial particle is treated as a discrete element interacting with other particles or domain boundaries. In this presented work, particle-particle and particle-wall interactions are handled using a Hertzian elastic body collision model. Results from two canonical particle-laden flows problems are presented to validate the implementation, followed by simulations for a two-way coupled embolus transport simulation inside a physiologically realistic vessel.

Key Words: Heart modeling, Multiphysics and multiscale models, Numerical simulations, Computational Medicine

We present recent advancements on multiphysics and multiscale models for the numerical simulation of the whole cardiac function. In particular, we detail our contributions to cardiac electromechanics of the ventricles and then of the whole heart. Specifically, we couple state–of–the art models for the electrophysiology of the tissue, mechanical activation at the cellular level, and the passive mechanical response of the muscle, thus yielding a coupled electromechanical problem within the active stress paradigm. Our multiscale model for cardiac electromechanics accounts for miscroscopic active force generation at the cellular level by means of model order reduction based on Machine Learning algorithms. In addition, our 3D electromechanical model is coupled with a 0D, closed-loop model of the systemic and pulmonary blood circulations, other than of the other cardiac chambers. We consider the space approximation of the Partial Differential Equations therein involved by means of the Finite Element method. We numerically solve the coupled electromechanics problem by exploiting intergrid transfer operators, as well as partitioned–staggered schemes for realizing the numerical coupling. We present and discuss numerical simulations, obtained in the high performance computing framework, of cardiac electromechanics problems in the human heart, both in physiological and pathological conditions. Finally, we also present a Machine Learning method that enables real-time numerical simulations of cardiac electromechanics.

This project has received funding from the European Research Council (ERC) under the European Union Horizon 2020 research and innovation programme: grant agreement No 740132, iHEART – "An integrated Heart Model tor the Simulation of the Cardiac Function", 2017–2022.

Quantifying the Range of Mechanical Stimuli from the Severity and Duration of Aortic Coarctation that Prevents Permanent Vascular Remodeling

Jamasp Azarnoosh Ph.D.[1*], Arash Ghorbannia M.S. [2], John F. LaDisa Jr. Ph.D.[3]

Key Words: *Coarctation of the aorta, Congenital cardiovascular defects, Hypertension, Fluid-structure interaction*

Coarctation of the aorta (CoA) is one of the most common congenital cardiovascular (CV) defects. Surgical repair of the coarctation is used to enhance lifespan from CV morbidity [1], but life expectancy is still lower than normal mainly due to refractory hypertension (HTN) even after successful treatment [2]. The current treatment guideline of a peak-to-peak blood pressure gradient (BPG_{pp}) ≤20 mmHg implemented clinically has revealed irreversible changes in arterial structure and function, yet revised guidelines have not been proposed [3]. Prior studies have been limited to older ages so the temporal evolution of mechanical stimuli at younger ages driving irreversible vascular remodeling are unknown [2]. We hypothesize that excessive coarctation-induced mechanical stimuli over time lead to changes in structure and function in the aorta and its branches, ultimately manifesting as HTN. The main objective of this work is to define specific ranges of mechanical stimuli from the severity and duration of CoA that prevent permanent remodeling (structure and function). Following IACUC approval, rabbits were exposed to BPG_{pp} severities ≤10, 11-20, and >20 mmHg for 1, 3, or 20 weeks by varying the severity and duration of CoA using permanent, dissolvable, and rapidly dissolvable sutures tied around the aorta at the sight CoA most often presents clinically. Longitudinal fluid-structure interaction (FSI) simulations over age were conducted in SimVascular (simvascular.github.io) using geometry and boundary conditions measured empirically for each group. Elastic modulus at younger ages was estimated in the simulation tuning process based on diameter variation from the systolic and diastolic phases measured during ultrasound imaging. Mechanical stimuli were then characterized including blood flow velocity patterns, medial tension, strain, and wall shear stress (WSS) indices. Preliminary data show vascular alternations such as thickening, stiffening, and dysfunction in the proximal region above the coarctation with increasing severity and/or duration of CoA. For instance, results for 20-week CoA with severity ≤10 suggest an increase in wall tension with age of ~10%, which drives changes in thickening and function. Upon quantification of mechanical stimuli from all groups, these methods will reveal the specific range of mechanical stimuli that avoid permanent vascular remodeling from CoA. The current work may then be implemented clinically via imaging and FSI modeling as part of protocols that limit the likelihood of HTN in CoA patients.

Key Words: *phase-contrast magnetic resonance imaging, fluid dynamics, pressure field reconstruction, wall shear stress*

This study introduces a novel wall shear stress (WSS) estimation method for 4D flow magnetic resonance imaging (MRI). The method improves the WSS accuracy by using the reconstructed pressure gradient and incorporating the flow-physics constraints of the conservation of mass and linear momentum to correct the velocity gradient estimation. The method was tested on synthetic 4D flow data of analytical Womersley flow and flow in cerebral aneurysms. The proposed method's performance was compared to the state-of-the-art method based on smooth-spline fitting of the velocity profile [1] as well as the WSS calculated from uncorrected velocity gradient. The proposed method improved the WSS accuracy by as much as 100% for the Womersley flow and reduced the underestimation of mean WSS by 39% to 50% for the synthetic aneurysmal flow. The method was further applied to *in vivo* 4D flow MRI data acquired in cerebral aneurysms. The predicted mean WSS using the proposed method was 31-50% higher than predictions using the other methods. This suggested improved WSS accuracy as a previous study showed that the WSS calculated from 4D flow MRI was underestimated by 40-60% in intracranial aneurysms due to limited spatial resolution [2]. The distribution of high-WSS regions predicted using the proposed method was consistent with patient-specific CFD results. The method was further applied to *in vivo* 4D flow data in aortas. The mean systolic WSS estimated by the proposed method was 5-8 Pa, which was 4-6 times higher than the results using the other methods. The range of WSS estimated using the proposed method was consistent with the previous CFD studies, and the predicted high-WSS regions showed an improved correlation with the vortical structures (VSs) at systole. The correlation between VSs and high WSS has also been observed in a previous investigation using CFD simulations [3]. The proposed pressure-gradient-based WSS estimation method improves the accuracy of WSS estimation from 4D flow MRI data, which can help predict blood vessel remodelling and progression of cardiovascular diseases.

Key Words: *TBI, Helmet Performance, Blast, Blunt Impact, Simulation*

The mild traumatic brain injury (mTBI) is one of the most common injuries to service members in recent conflicts. Combat helmets have been designed and evaluated to perform against ballistic and blunt impact threats, but not blast threats. An optimal design of combat helmet considering blunt, ballistic impacts and blast effects is a key requirement to improve the head protection against mTBI. Combat helmets are usually designed based on costly and time consuming laboratory tests. Computational models can offer insights in understanding the force transmission through the head-helmet system into the brain and underlying mechanism of brain injury, and help the development of effective protective design. The objective of this work is to develop a design approach integrating the effect of both blast and blunt threats to a helmet system by utilizing multi-physics computational tools and representative human head and helmet models. The high-fidelity computational models were used to capture the dynamic response of the composite shell, suspension pads, retention straps and head. We used a validated human head model to represent the warfighter's head. The helmet composite shell was represented by an orthotropic elasto-plastic material model. A strain rate dependent model was employed for pad suspension material. Available dynamic loading data was used to calibrate the material parameters. Multiple helmet system configurations subjected to blast and blunt loadings with a combination of loading magnitude and orientation were considered to quantify their influence on brain biomechanical response. Parametric studies were carried out to assess energy absorption for different suspension geometry and material morphology for different loadings. The resulting brain responses in terms of pressure, stress, strain, and strain rate as well as the head acceleration were used with published injury criteria to characterize the helmet system performance through a single metric for each threat type. Approaches to combine single-threat metrics to allow aggregating performance against multiple threats were discussed.

A Soft-Tissue Driven Bone Remodelling Algorithm in Mandibular Residual Ridge Resorption Based on Patient CT Image Data over 5 Years

Key Words: *Spatial Image Quantification, Soft-tissue Induced Bone Remodelling, Predictive Simulation*

Mucosa is a thin layer of nonuniform soft tissue covering bones in the oral cavity. It consists of abundant vasculature and nerve systems, acting as the gateway of material exchange to bone and providing important sensation in mastication. In the edentulous population, the residual ridge of a mandible faces significant risks of progressive and continuous bone loss, due to lack of mechanical stimulation from the missing teeth. A prosthodontic overdenture is often fitted to the mandible or maxilla to restore the masticatory function; but in the meantime, it exerts non-physiological loading to the mucosa beneath. While this thin soft issue bears and dissipates mastication forces to some extent, the compression has been found to potentially cause localised ischemia and inflammation with increasing hydrostatic pressures in the mucosa [1,2]. This ill-suited biomechanical condition is believed to accelerate this unwanted residual ridge resorption (RRR) [3]. However, the role of the biomechanical stimulation from the soft tissue has not yet been quantified or separated from the natural bone loss [4,5].

Our study recruited 8 implant-retained overdenture patients with follow-ups over 5 years, primarily aiming to elucidate the governing relationship between the RRR and the local hydrostatic pressure (σ_H) in the mucosa and then, to develop a predictive algorithm of this dynamic process. We first developed a computational framework for quantifying the localised bone profile changes to differentiate the natural and the prosthesis-induced bone loss. Patient-specific models were created from the segmented CT image sets, and the hydrostatic pressure distribution and changes in the mucosa was evaluated. The profile changes were then correlated to the local σ_H. Our results showed the total resorption under denture compression was most severe ($p < 0.001$) during the first year with an average ridge height reduction of 0.53 ± 0.08 mm. By using the resorption in the uncompressed regions as control, we found 40.6% of the resorption was induced by the compression onto the soft tissue. During the 2nd to 5th years, the total resorption gradually decreased to 0.10 ± 0.01 mm per year, and the natural bone loss was the dominant. The correlation (R^2) between RRR and the local σ_H varies between 0.55 and 0.57 with a power-law function, which has a constant term representing the natural bone loss. Based on this correlation, we can further develop a soft-tissue driven bone remodelling algorithm. In addition, our findings provide a biomechanical basis for gaining new insights into the mechanobiological responses in the soft-hard tissue interfaces to external forces, thereby benefiting the treatment.

Key Words: *Bone, Ecology, Evolution, Homeostasis, Computational*

The bone is an incredibly dynamic organ whose homeostasis emerges from the interactions between a large variety of resident cell types such as osteocytes, macrophages, mesenchymal stem cells, osteoclasts, osteoblasts, etc. These interactions are facilitated by factors and signals that help orchestrate bone dynamics. While purely experimental approaches have provided us with intriguing data and reductionistic insights, mathematical and computational models can integrate multiscale data and biological insights in ways that other models cannot. Here we use an agent-based model that captures the ecological and evolutionary features of the bone ecosystem. The models are hypothesis-driven and hypothesis-generating, they are parameterized with the help of experimental models and calibrated to capture bone's dynamic homeostasis. This model provides us with a high temporal and spatial resolution view of the bone and allows us to understand not only how it can naturally change over time but how tumors can start (or metastasize) and how the interactions between the tumor cells and the bone environment shape the Darwinian dynamics that characterize cancer progression. With the help of this model we have studied both the initiation of multiple myeloma as well as prostate cancer metastases in the bone. Extending this model to consider cancer treatments such as proteosome inhibitors (for myeloma) and androgen deprivation therapies (for prostate cancer) our model can also explain the impact of the bone ecosystem in the emergence of treatment resistance in bone cancers.

Effects of Mineralisation on Collagen Ultrastructure and Micromechanics

Key Words: *Fibrillar network, Mineralized collagen, Turkey Leg Tendon,*

Collagen mineralisation plays a critical role in the growth, development, and ageing of tissues, including bone and its interfaces with cartilage, ligament, and tendon. One or multiple cell groups can be involved in the process, depositing mineral into the collagen matrix secreted. The soft and hard components must maintain a delicate equilibrium in order to give rise to the highly regulated and multiscale architecture, thereby meeting the biomechanical demands, such as fracture resistance [1]. Disruption of the mineralisation process is associated with many disorders like osteosclerosis, craniosynostosis, and osteogenesis imperfecta. Although extensive efforts have been dedicated to studying the mechanism of mineralisation in the intrafibrillar and interfibrillar space of collagen [2], we still have lack of understanding as to how the collagen structure changes in this process as well as the response to mechanical loading. The recent development in polarisation-resolved second harmonic generation (pSHG) microscopy revealed a hierarchical arrangement of collagen fibrillar and molecular organisation [3]. This fast-scanning label-free method allows capturing the ultrastructural features of collagen and the responses to loading.

Our study is to investigate the multiscale structural organisation and mechanical response of collagen at different degrees of mineralisation. We adopted turkey leg tendons, a widely and readily available model for studying collagen mineralisation. This avian tendon model exhibits a gradient of mineralisation in the same specimen. 4 fresh and unprocessed specimens were dissected from 20-week-old turkeys. The specimens were first imaged with x-ray absorptiometry to identify the mineralisation in the tissue. Half of the samples were individually mounted to a custom-built multiphoton microscope coupled with a tensile loading rig, on which pSHG and two-photon excitation fluorescence (TPEF) were acquired simultaneously. From pSHG data, the principal orientations and fibre dispersions of collagen were evaluated. From TPEF, the distribution and orientation of elastin were correlatively evaluated with respect to the collagen. The scans were performed under unloaded and statically loaded states at four regions of interest, namely unmineralised, fully mineralised, highly mineralised, and slightly mineralised regions. The changes in the orientation and dispersions of collagens were quantified. The other half of the specimens were scanned with x-ray diffraction on the VMXi beamline at the Diamond Light Source. This technique provides direct measurements of the orientations and anisotropy of collagen fibrils and mineral particles in specimens, as well as their changes as the responses to loading. Strong heterogeneities of collagen and elastin organisation were observed in both multiphoton and diffraction images, among and within different regions of interest along the gradient of mineralisation. The mechanical responses of the constituents will be evaluated as the next stage of this project.

Encoding the Setpoint of Bone Functional Adaptation With Osteocytes

Yves Pauchard[1*] **and Pascal Buenzli**[2]

Key Words: bone tissue regulation, mechanical adaptation, osteocyte, mechanostat, bone remodelling

The osteocyte network in bone is believed to play an important role for how bone tissues sense and respond to mechanical stimulation. Yet, the functional adaptation of bone is often conceptualised as a simple bone response to mechanical stimuli, such as Wolff's law or Frost's mechanostat [1], which are based on purely mechanical variables and take no account of cellular aspects of the mechanical reference state (setpoint). In this contribution, we present a theory of bone tissue sensing and adaptation based on osteocytes to provide new understanding of the role played by osteocyte signals in bone tissue regulation. This theory is based on prior work [2] and extends Frost's mechanostat theory by linking the mechanical setpoint to osteocyte properties. It further assumes that setpoint adaptation is due to the replacement of osteocytes during remodelling. We present numerical simulations to explore how mechanobiological response curves (Wolff's laws) are modulated by setpoint adaptation due to osteocyte replacement during remodelling, and by disruptions to osteocyte signals due to loss of osteocytes with age. We find that setpoint adaptation could have significant consequences, including (i) long-term irreversibility of mechanical sensitivity, which is relevant to exercise in age-related bone loss and to multi-mission astronauts; and (ii) hysteresis in Wolff's laws, which may be experimentally observable.

Large mandibular defects resulted from trauma, tumour, or osteoradionecrosis represents some common and critical morbidity in the maxillofacial reconstruction. Using osteosynthesis devices to bridge the defect with fibula free flap (FFF) has become a major approach for mandibular reconstruction, owing to the advantages of adequate bone length, low donor site damage, and an abundant periosteal blood supply[1]. However, failure of these devices due to fatigue under cyclic loading has been recognized as a primary concern on therapeutic longevity. In this study, we develop a computational approach for modelling fatigue process in the reconstruction plate based upon the eXtended Finite Element Method (XFEM). When a reconstruction plate is placed, the bone would remodel itself continuously; thus, the stiffness of the prosthetic system would change over time [2] The crack initiation and propagation due to the excessive loads will affect the stiffness of the plate and consequently bone remodelling process by varying the mechanical loading transfer on the bone. To investigate the interaction between fatigue process and bone remodelling, we propose a time-dependent fatigue analysis approach by taking into account the effect of the Wolff's law-based bone remodelling process. The influence of biting force measured over treatment time on the fatigue life of fixation plate and bone remodelling is also analysed. Under various occlusal loadings, the interactive effects between fatigue crack growth and bone remodelling are investigated to obtain some new insights into the design of prosthetic devices. This study showcases an effective approach for predicting fatigue failure of prosthetic devices *in-silico*, thereby guiding design optimisation of patient-specific prosthetic devices to ensure their longevity.

Osteonal pores in cortical bone provide highly confined spaces infilled by new bone during bone remodelling. The geometric crowding and spreading of new tissue material at concave and convex areas of the bone surface induce strong geometric control on the rate of growth of new bone tissue in these pores. A record of the differential growth rates is provided by the concentric rings of lamellae seen in the new bone. The lamellae indicate past surface locations, and their arrangement and geometry give insights into bone generation mechanisms [1]. However, these experimental data comprise a tangled combination of geometric influences and cell behavioural influences of bone tissue growth.

To disentangle these influences, we build on a mathematical model of the geometric control of cells growing new tissue, based on rigorous principles of material balance on moving boundaries [2]. The mathematical model enables us to factor out the mechanistic influence of geometric crowding on growth rate in the experimental data. By comparing numerical simulations of pore infilling with experimental osteon geometries quantitatively, we gain insights into the diffusive and active/inactive behaviours of the cells in a variety of regular and irregular osteonal pores.

Nanoindentation Protocol for Identifying Elasticity of Periodontal Ligament

Yo Shibata* **and Chie Watanabe**

Showa University School of Dentistry, 1-5-8, Hatanodai, Shinagawa-ku, Tokyo 1428555, Japan, yookun@dent.showa-u.ac.jp

Key Words: *Nanoindentation, Periodontal ligament, Mechanical properties, Soft tissues*

The load bearing integrity of tooth against chewing stresses within alveolar bone is most likely associated with instantaneous stiffness and subsequent time-dependent stress relaxation of periodontal ligament (PDL). Despite it comprising only thin (hundreds of microns) outer membrane of tooth root, PDL characteristics meet the multifunctional criterial, hence identifying the mechanical properties of PDL is an important insight to conceptualize new load bearing biomaterials and/or industrial applications. A major difficulty of this concept is lack of precise first-hand data of PDL at tissue level. Here we demonstrate a new nanoindentation protocol for PDL and its validations.

This study adopted 7-week-old male BALB/c mice as the animal subject and euthanized it in a carbon dioxide chamber. Immediately after the sacrifice of the animal, the hemi-mandible, containing three molars and one incisor, was excised and dissected at the fibrous mandibular symphysis. All the animal procedures in this study were developed in accordance with Guiding Principles for the care and use of Animals.These specimens were transversely cross sectioned using a microtome at the level of cervical line as well as the approximately mid-root level of the molars, exposing the PDL at different anatomical position for nanoindentations.

Nanoindentation tests were carried out using a quantitative nanomechanical test instrument (TI 950 TriboIndenter, Hysitron, Inc, Eden Prairie, MN, USA). A diamond flat-end indenter with 10 μm diameter was used for corresponding to required measurement size for fiber bundles. The indenter was attached to the high bandwidth transducer (nanoDMA III, Hysitron Inc.) allowing dynamic mechanical analysis (DMA) on PDL. The load applied to the PDL was controlled using a feedback closed-loop load-control algorithm for all the tests. Force-displacement curves were recorded under loading rates of 10 μN/s with a maximum force at 50 μN. The loading portion was followed by 2 sec holding with superimposed dynamic oscillations at a frequency of 200 Hz and displacement amplitude of 1-2 nm. The dynamic sinusoidal oscillation captures contact (storage) stiffness almost associated with loading strain so that storage moduli were measurable. A validation was also carried out using a quasi-static load function, using the fast loading/unloading rate (50 μN/0.1s) so that elastic and viscoelastic responses can be discerned, since viscus portion cannot be responsible against such fast loading/unloading strains.

Both calculated storage moduli and quasi-static elastic moduli were comparable, hence instantaneous elastic modulus of PDL at fiber bundle level is around 100 MPa irrespective of loading rates. Further investigation of delayed viscoelastic response with a combination of FEA and first-hand nanoindentation data would be desirable to fully understand the nature of PDL.

Regional Variations in Articular Cartilage Ultrastructure and Micromechanics

Jingrui Hu[1*], Keke Zheng[1], Eve Nebbiolo[1], Jessica Mansfield[1], Ellen Green[1], Peter Winlove[1], Ben Sherlock[1], and Junning Chen[1]

[1]University of Exeter, Stocker Rd, Exeter EX4 4PY, J.Hu1@exeter.ac.uk

Key Words: *Articular cartilage, regional variations, micromechanics, pSHG,*

Central to the functions in load bearing and mobility, the biomechanical properties of articular cartilage arise due to its extracellular matrix (ECM) consisting of a collagenous network interacting with an interstitial fluid rich in proteoglycans [1]. The recent development in analysing the polarisation-dependence of second-harmonic generation (pSHG) imaging revealed hierarchical complexities of collagen fibrillar and intrafibrillar organisation [2, 3]. This advance technique allows examination of the well-known zonal variations along with the depth of the tissue across length scales. The fast-scanning speed also provides capability of visualising dynamic responses to external loading, to which both levels of structural organisation were found highly sensitive. However, a quantitative relationship between the collagen organisation and the mechanical response has not yet been established. Apart from the zonal variation, different compartments and regions of the joint experience different types of mechanical loading [4]. We hypothesize that the collagen organisation is tailored to its local biomechanical environment at different anatomical locations of the joint, and such organisational variation is also manifested in their susceptibility to injury and degenerative disease, like osteoarthritis.

The overarching aim of our study is to establish a quantitative relationship between the cartilage structural organisation and its biomechanical function by comparing different regions of articular joints. A pair of bovine metacarpophalangeal (MCP) joints were acquired from a local abattoir, and 24 explants in cuboid shapes were harvested from the medial, lateral, and patella-femoral compartments. We first map the longitudinal cross-section of the explants with pSHG and evaluated the structural variations among three zones (superficial, transitional, and deep zones) by quantifying the principal angles and degrees of dispersion of collagen. Next, the same specimens were mounted and loaded on a custom-built rig integrated with our pSHG microscope, to visualise structural responses under two levels of tissue strains applied at 8% and 16%. These two strain levels present a medium and an extreme case in normal activities, respectively. The structural responses were evaluated in terms of the re-orientation and re-alignment of the collagen fibrils.

A numerical study on the generic flexible-cell focus in viscoelastic flows

Key Words: Immersed boundary method, fluid-structure interaction, viscoelastic flow

The generic flexible-cell focus in viscoelastic flows through a contraction-expansion microchannel is investigated by an immersed boundary-lattice Boltzmann method [1, 2]. The effects of the fluid viscoelasticity, the initial position of the cell and the confinement of the microchannel on the cell migration are evaluated. It is found that the migration of the cell includes two stages: (a) the migration in the center plain and (b) the migration away from the center plain. At stage (a), the cell may focus to one trajectory or different trajectories (from different initial positions) depending on the viscoelasticity of the fluid and the confinement of the microchannel. The viscoelasticity of the fluid and the confinement of the microchannel facilitate the focusing of the cell. At stage (b), the cell focuses to a steady trajectory after a long-term migration. The equilibrium projected trajectory of the cell (on a cross section of the microchannel) forms a ring, and the stronger viscoelasticity of the fluid generally induces a higher equilibrium trajectory of the cell.

Agent-Based Models of Biophysical Interactions in Multicellular Systems

Paul Macklin[1]

[1] Indiana University, 700 N Woodlawn Ave. Bloomington, IN 47401, USA, macklinp@iu.edu

Key Words: Agent-Based Model, Open Source, Multiscale, Multicellular Systems, PhysiCell

Multicellular systems–ranging from ecosystems of single-cell organisms to healthy and diseased tissues–are dynamical multiscale systems where complexity emerges from myraid cell-cell and cell-environment interactions. Cells can read chemical and mechanical signals in their environment, and process them via complex intracellular networks to drive changes in their metabolism, proliferation, death, migration, mechanical characteristics, and secretion of chemical signals to communicate with other cells [1]. Chemical and mechanical signals can propagate through over fast time scales across short distances (e.g., by contact), or over slow time scales over larger distances (e.g., by diffusion). Simulation models can act as "virtual laboratories" to help understand these highly nonlinear systems, but cellular-scale heterogeneity and stochasticity sometimes require that such models incorporate cell-scale behaviors and interactions.

After introducing cell-based models [2], we will describe PhysiCell [3]: an open source, cross-platform 3-D simulation platform that models individual cells as discrete agents in complex chemical microenvironments governed by reaction-diffusion equations. We will describe general formulations for cell-cell interactions by contact, mechanics, and chemical communication. Using this repertoire of interactions, we will explore a broad range of models including mechanics-driven arrest of cancer metastases [4], hypoxia-driven cancer invasion [5], predator-prey systems, oscillations in cell colonies, cell specialization, cancer-immune interactions [6], and multiscale modeling of immune response to viral infections [7]. We will also describe how PhysiCell can be combined with intracellular signaling models into multiscale models that span from molecular to tissue scales [8]. We will conclude by demonstrating recent advances to create a simplified "signal-response" representation of cell-cell interactions, and to use this to create graphical "expert-in-the-loop" model design tools for multidisciplinary teams.

Key Words: *Actin, Myosin, Bleb, Cell, Actomyosin contractility*

Changes in cell shapes are mostly driven by forces generated from the cytoskeleton. Recently, several in vitro experiments developed a synthetic cell-like system consisting of actin networks, cross-linking proteins, and myosin motors encapsulated by lipid vesicles or water droplets in order to study cell-scale behaviors facilitated by forces generated from actomyosin networks. However, these experiments are very hard to conduct, thus preventing exploration of wide parametric spaces. To overcome experimental limits and thus perform extensive parametric studies, we developed a novel agent-based model for a minimal cell-like structure comprised of discrete actomyosin cortex, osmotic pressure, and cell membrane simplified into a triangulated mesh. The cortex is coupled to the cell membrane to various extents via cross-linking proteins. Using this model, we found how cell shapes are regulated by a competition between actomyosin contractility that tends to induce contraction and osmotic pressure that tends to lead to expansion. We demonstrated that bulge that mimics cell blebs can be formed when the coupling level between the cortex and the membrane is intermediate. Our results provide insights into understanding how cell shapes are regulated under diverse conditions.

Computational Modeling of Pressure-Driven Cell Motility under Confinement

Key Words: *Cell mechanics, Fluid-structure interaction, Regularized Stokeslets*

Cell migration is critical for many vital processes, such as embryogenesis and tissue repair, as well as harmful processes, such as cancer cell metastasis. In experiments, cells have been shown to exhibit different migration strategies based on the properties of their external environment [1]. For example, cells migrating through a 3D gel use myosin-driven rear contraction for motility [2]. In [3], cells migrate using round membrane protrusions called blebs while confined between two surfaces, a gel and glass coverslip. Additionally, recent experiments demonstrate that cells do not need to adhere to the channel walls in order to migrate under confinement [4], yet it is unclear how traction forces are coordinated in space and time to generate motion. Dynamic 2D computational models of a migrating cell using intracellular pressure gradients generated by (1) rear contraction and (2) blebbing in a narrow channel are presented. The cell model consists of an elastic membrane, poro-(visco)elastic cortex, membrane-cortex adhesion, and the fluid cytoplasm. Evolution equations for the actin density of the cortex are included for modeling bleb retraction. The channel walls are modelled as rigid structures with different shapes. The model is formulated using the method of regularized Stokeslets [5]. Results show that the cell cannot effectively migrate when the cortex is modeled as a poroelastic structure using repeated cycles of either rear contraction or blebbing, even when the channel walls are asymmetric. Simulation data show cells can migrate in symmetric and asymmetric straight channel walls only if the cortical turnover is included by modelling the cortex as a poro-viscoelastic structure.

yingzhang@brandeis.edu and https://sites.google.com/brandeis.edu/yzhang

Key Words: Fluid-structure interaction, Blood cell motion, Wall-induced migration

Many fluid-structure interactions in biology involve the near-contact of elastic objects separated by a thin layer of viscous fluid. In viscous fluids such as blood, deformable objects can acquire lift forces and migrate away from walls, a phenomenon known as wall-induced migration [1].

Blood vessels are lined by an endothelial surface layer that has a thickness up to 1 micron. This layer has physiological roles in fluid-solute exchange and coagulation response, and may also influence blood flow through interactions with the suspended blood cells [2].

To simulate the interaction of red blood cells with vessel walls, we use the immersed boundary method [3] to explore the effects on red blood cell lift of surface roughness and changes in the endothelial surface layer thickness that arise in pathological conditions such as sepsis. Perturbations in the lift force lead to changes in the cell free layer, which we speculate may have consequences on the spatial distribution of platelets, which indicates potential importance of the endothelial surface layer.

Microscale flow dynamics of blood cells in health and disease

Xuejin Li[1*]

[1] Department of Engineering Mechanics, Zhejiang University, Hangzhou 310027, P. R. China, xuejin_li@zju.edu.cn

Key Words: *Red blood cells, Blood disorder, Flow dynamics, Multiscale modelling*

In humans, normal red blood cells (RBCs) are flexible and deformable. The extreme deformability allows them to squeeze through narrow capillaries without any damage. However, in many blood disorders, the membrane defects of diseased RBCs cause the impaired blood flow and other pathophysiological aspects of disease-related vascular complications. By combining dynamic microfluidic experiments with multiscale simulations, we investigated the biomechanical properties and flow dynamics of RBCs in health and disease. We showed that the RBC undergoes a severe deformation as it traverse microvascular passages, and the membrane defects of the RBCs play a crucial role in the regulation of blood flow.

Modeling and Simulation of Osteocyte-Fluid Interaction

Luoding Zhu[1,*], Jared Barber[1], Sungsoo Na[2], and Hiroki Yokota[2]
[1] Department of Mathematical Sciences, Indiana University Purdue University Indianapolis, 402 N Blackford Street, LD 270, Indianapolis, IN 46202 {luozhu, jarobarb}@iupui.edu
[2] Department of Biomedical Engineering, Indiana University Purdue University Indianapolis, 723 W Michigan Street, SL 220, Indianapolis, IN 46202 {sungna,hyokota}@iupui.edu

Key Words: *Osteocyte, Mathematical Modelling, Lattice Boltzmann, Immersed Boundary*

The osteocyte is a bone cell that is responsible for mechanotransduction and guides growth and remodeling in bone. The cell consists of a nucleus, cytoskeleton, cytoplasm, plasma membrane, and numerous dendritic cellular processes. It is encased in a lacuna in the lacunar-canalicular network that permeates the bone matrix. The interstices between the cell and the bone matrix are filled with a salt-water-like fluid and the pericellular matrix (PCM), which consists of cell-associated proteins surrounding the cell. When the bone is mechanically loaded, the interstitial fluid is forced through the PCM, introducing stresses on the cell. Experiments suggest that those stresses and associated strains are amplified approximately ten-fold compared to the macroscale stress and strain that occur during normal motion. The mechanism of this stress amplification is not well characterized. *In vivo* experiments are challenging to conduct because of the complexity of the osteocyte's microenvironment. Modeling and simulation, however, can provide a viable approach for shedding insights into the force amplification that occurs in the system.

Here, we use two mathematical models to characterize the force amplification mechanism in osteocytes. In the first two-dimensional model, the osteocyte's main body is modeled as a deformable ellipse composed of multiple interconnecting flexible fibers, which represent the membrane and the internal cytoskeleton, immersed in viscous flow, representing the cell's cytoplasm/interior. The cellular processes are modeled as multiple flexible fibers attached to the main body that are immersed in a viscous incompressible fluid that represents the surrounding interstitial fluid of the lacunar-canalicular network. That fluid is encased in the bone matrix that is modeled as a rigid body whose wall bounds the fluid region. To approximate typical motion, a random set of canaliculi are modeled as outlets while the remaining canaliculi are modeled as inlets. We consider the influence of the number and geometry of the canaliculi on the wall shear and normal stress on the osteocyte membrane and processes. The second three-dimensional model is based on images taken during laboratory experiments. The osteocyte is represented as a network of connected tetrahedrons immersed in a viscous incompressible fluid, with different refinement levels for the membrane, cytoskeleton, and nucleus. Each tetrahedral edge is made of a deformable fiber. The model considers how stress and strain are distributed throughout the osteocyte's main body when external flow exerts force on the cell. In both models, the viscous flow is modeled by the lattice Boltzmann equations (D2Q9 and D3Q19) and the fluid-structure interaction is modeled by the immersed boundary method.

Numerical simulation of active surface dynamics leading to cell division and migration

Key Words: *Active surface, Free-boundary problem, surface-bulk coupling, viscoelastic surface, cell shape dynamics*

Mechanochemical processes play a crucial role during morphogenesis, the formation of complex shapes and tissues out of a single cell. On the cellular level, the actomyosin cortex governs shape and shape changes. This thin layer of active material underneath the cell surface exerts an active contractile tension, the strength of which being controlled by the concentration of force-generating molecules. Advective transport of such molecules leads to a complex interplay of hydrodynamics and molecule concentration which gives rise to pattern formation and self-organized shape dynamics [1,2].
In this talk, we present a numerical model to simulate an active surface immersed in viscous fluids. The cortex is modelled as a viscoelastic surface material [3], described by a freely evolving Finite-Element grid. The dynamics are coupled to a surface concentration equation of force-generating molecules (actomyosin).
We show the resulting mechanochemical patterns which emerge in different parameter configurations. This patterning goes along with surface and intracellular flows which drive cell division or cell migration, accompanied by impressive cell shape dynamics. We compare the results to linear stability analysis [2] and experimental data.

Key Words: Cell-wall, Saccharomyces cerevisiae, Growth, Turgor pressure, Large deformations

Growth is a phenomenon that occurs in almost all living cells. It is essential for important cellular events such as organism development and cell division. In particular, *Saccharomyces cerevisiae* yeast has been one of the preferred organisms for the study of growth [1]. Yeast cells polarize their growth in response to both external and internal stimuli. In the present study, focus is made on internal ones. Being walled cells, they possess high internal turgor pressure that allows them to grow and survive in the environment.

A theoretical and numerical modeling is derived to describe this growth. Yeasts are herein regarded as axisymmetrical shells and, in view of their soft nature, a finite strain approcah is adopted. The kinematical choice is based on the multiplicative decomposition of the deformation gradient into an elastic part and growth part. It is shown how continuum thermodynamics is crucial in setting convenient forms for the coupling between stress and growth, e.g. [2]. As a modeling example, an Ogden-type constitutive relation is used for the elastic part, and for the growth evolution, a potential is introduced that takes into account the stress stimulation through a growth threshold and a characteristic time parameters.

The whole framework is embedded into a finite element context. For the shell kinematics, use is made of the quasi-Kirchhoff type theory for thin shells of revolution derived in, e.g. [3]. In this case, the meridional and circumferential strains are regarded as principal. Hence, this allows for an easy use of a theory based on principal stretches of the Ogden-type. Representative numerical simulations are given that show, among others, the influence of the turgor pressure as a stimulus for growth, and the influence of the characteristic time for its kinetics.

Phase-Field Model of Vesicle Motion and Deformation and Its Computation

Zhiliang Xu[1*]

[1] Department of Applied Mathematics and Statistics, University of Notre Dame, Notre Dame, IN 46556, USA. zxu2@nd.edu (https://www3.nd.edu/~zxu2/)

Key Words: *Multiphysics Problems, phase-field modeling*

A thermodynamically consistent phase-field model is introduced for simulating motion and shape transformation of vesicles under flow conditions. In particular, a general slip boundary condition is used to describe the interaction between vesicles and the wall of the fluid domain. A second-order accurate in both space and time C0 finite element method is proposed to solve the model governing equations. Various numerical tests confirm the convergence, energy stability, and conservation of mass and surface area of cells of the proposed scheme. Vesicles with different mechanical properties are also used to explain the pathological risk for patients with sickle cell disease.

The Effects of Vessel Wall Proteins on Red Blood Cell Dynamics at Diverging Vessel Bifurcations

Jared Barber[1*] and Carlson Triebold[1]

[1] Department of Mathematical Sciences, Indiana University-Purdue University Indianapolis, 402 N Blackford Street, LD 270, Indianapolis, IN 46202 {jarobarb, cbtriebo}@iupui.edu

Key Words: *Bifurcation, Endothelial surface layer, Red blood cell mechanics, Capillary flow*

Experiments have shown that red blood cells (RBCs) are nonuniformly distributed throughout the microvasculature. With RBCs making up approximately forty to forty-five percent of blood, this has important consequences for transport of materials such as oxygen (carried by RBCs), nutrients, other cells, and drugs. In nonuniform partitioning at diverging vessel bifurcations, where blood flows from one vessel into two downstream vessel branches, downstream branches with higher percentage flow regularly claim an even higher percentage of RBCs in that branch. This phenomenon plays a significant role in the earlier mentioned nonuniform distribution of RBCs throughout the microvasculature.

While many studies have considered different aspects of partitioning, few have considered the effects of a protein layer that coats the vessel wall often referred to as the endothelial glycocalyx layer, glycocalyx, and/or endothelial surface layer (ESL). The ESL has been increasingly recognized as being important with identification of its role in overall vessel flow resistance and in general cell adhesion to vessel walls. Despite this increasing recognition, studies have not yet explicitly targeted the potential effects of this important layer on RBC dynamics during partitioning.

To better understand how the ESL may affect partitioning, we constructed a computational model of RBCs passing one at a time through a bifurcation lined with a 1 micron thick ESL. RBCs are represented by an interconnected set of damped springs. The surrounding fluid is modelled using the Stokes flow equations. The ESL is modelled as a porous media that resists compression. The system is solved using a finite element solver that couples the three systems together. Decreasing the ESL's hydraulic resistivity and/or its resistance to compression generated more nonuniform partitioning. We also considered how ESL properties affected RBC deformation and penetration of the ESL. We found that decreasing the ESL's hydraulic resistivity and/or its resistance to compression increased RBC penetration of the ESL and, usually, decreased RBC deformation. We will also share preliminary results on how varying ESL properties affect RBC interactions with each other as they pass through a bifurcation. While all results are limited to very low hematocrits and a somewhat specific setting, they provide a strong start towards more fully characterizing ESL-RBC interactions including effects on RBC deformation dependent activity such as release of vasodilators and on RBC adhesion assisted clotting.

A Novel Chemo-Mechano-Biological Model of Osteoarthritic Cartilage

Key Words: *articular cartilage, mechanobiology, growth and remodeling, mathematical model*

Nearly 20% of people in the US suffer from osteoarthritis (OA) affecting the quality of life through pain, functional limitations, lost earnings, anxiety, and depression – yet we still do not understand the cause nor progression of the disease. While mechanical stimuli helps to maintain the healthy status of cartilage, overloading (e.g., trauma) and reduced loading (e.g., immobilization) causes upregulation of catabolic cytokines and downregulation of anabolic growth factors resulting in morphological and mechanical changes (e.g., softening, fibrillation, ulceration, and erosion). Current investigations of the effects of mechanical loading on cartilage – including both *in vitro* experiments with human cartilage and *in vivo* animal models – fall short of true human physiological relevance. Current mathematical models of signalling pathways lack mechanical inputs, while the biomechanical models lack the effects of cytokines. Here we propose a novel chemo-mechano-biological mathematical model including anisotropic, volumetric changes affecting the load-bearing behavior of osteoarthritic cartilage.

Leveraging our constitutive model for cartilage [1] we establish evolution equations for key chemical species and solid constituents [2], whereby the progression of OA results in volume loss normal to the articular surface [3]. We simulate six physically relevant conditions in the knee over 30 months: both normal walking and immobilization in health or after injury, and two therapeutic interventions after injury. Our model predicts homeostasis (i.e., no changes in the constituents or cytokines) for healthy individuals walking normally. Immobilization of healthy individuals increases both cytokines and loss of mass/volume of key constituents. The adverse effects of injury improve with normal walking but worsen with immobilization. Therapeutic interventions produce improvements in the mass of key constituents. Our proposed framework is a first step towards a new class of computational tools that consider, for the first time, the turnover and production of constituents and cytokines within cartilage in health and disease.

Key Words: *Articular Cartilage, In silico Modelling, Finite Element Analysis, Mechanobiology*

Osteoarthritis (OA) is a multifactorial disease characterized by cartilage degeneration [1]. *In vitro* and *in vivo* animal experiments show that altered mechanical loading is a driver of OA onset and progression [2, 3]. However, a thorough understanding of the mechanisms behind cartilage degenerative changes and their interactions in healthy and OA cartilage remains to be further elucidated.

In the "Happy Joints" project we use *in silico* modelling as a bridge between *in vitro* and *in vivo* experiments investigating the role of mechanical loading on cartilage homeostasis. Our musculoskeletal computational models can estimate realistic mechanical stimuli as seen in the joint, as well as validate and optimize parameters used in *in vitro* and *in vivo* experimental designs. We implement cartilage mechano-regulatory algorithms reflecting healthy and OA cartilage biology in *in silico* models through adaptive finite element approaches [4]. These models relate the mechanical loading on cartilage to tissue degeneration and regeneration based on observations from *in vitro* bioreactor experiments and biological analysis. After calibration and validation with experimental data, the adaptive finite element models can predict cartilage tissue adaptation upon mechanical loading. Our adaptive modelling results show that collagen fibril degradation has a unique role in OA progression followed by injurious mechanical loading, as it contributes to developing a cartilage tissue degeneration loop once the collagen degradation has been started.

This work relies on a multidisciplinary approach combining expertise from biology, tissue engineering, computational, biomechanical and clinical fields, in a new interdisciplinary research line called "mechanomics". In the short term, our computational models can help reduce *in vitro* experiments and contribute to the 3Rs in animal research (replacement, reduction, refinement). In the long term, validated models of cartilage mechano-regulation in humans have the potential to be translated into a clinical setting to predict cartilage adaptation after interventions, such as tissue engineering approaches, surgery, exercise and drugs.

Key Words: *Cold plasma jet, Cytotoxic drug, Melanoma, In-silico, Agent-based model*

Atmospheric Pressure Plasma Jet (APPJ) is very promising in such that it can effectively be used against cancer. Plasma jet produces reactive species, ultra-violet radiation, and intense electric fields, which affect the functionality of biological matter, avoiding thermal damage due to the low APPJ gas temperature [1]. In various *in-vitro* and *in-vivo* studies, APPJ are applied either directly (i.e., cancer cells cultured in media subjected to APPJ) or indirectly (i.e., APPJ-treated cell media injected to cancers). Furthermore, APPJ can be used as adjuvant therapies with other cancer treatment modalities to achieve enhanced therapeutic outcomes [2]. To date, very few research works have investigated APPJ effect on neoplasia using *in-silico* models.

In this work we present a novel *in-silico* model to simulate murine melanoma cancer cell response to helium APPJ or/and doxorubicin drug (DOX). The *in-silico* considers an agent-based modelling approach [3]. The model is informed by relevant *in-vitro* experiments on cancer-cell viability that provide information on cell number development during incubation, and probability values for apoptosis and mitosis following subjection to a plasma-conditioned medium, DOX, and DOX combined with APPJ. The simulations highlight the impact on cell number, apoptosis or/and mitosis of each treatment scenario, depending on plasma-treatment duration and DOX concentration. The *in-silico* results agree with the corresponding *in-vitro* data. The proposed modelling approach offers great potential to predicting cancer-cell behaviour upon exposure to APPJ or/and chemotherapeutics by quantifying cell biomechanics – this demonstrates the capacity of *in-silico* in plasma (cancer) medicine.

Key Words: *articular cartilage, theory of porous media, FE^2 methods, microdamage*

While microcracks in bone have been characterized extensively, and sub-millimeter-scale surface fissures are well known for early to advanced osteoarthritis (OA), we recently demonstrated that low-energy impact usually considered non-injurious can in fact cause micrometer-scale cracks in the collagen network of human cartilage [1]. While pre-clinical OA may originate with microcracks in the network of collagen, it is likely crack propagation in the extracellular matrix (ECM) that initiates the cascade of OA degeneration. However, the extent of microcrack propagation during repetitive mechanical loads to cartilage during normal daily activities is unknown. Finite element (FE) models are well-established at the macro (e.g. joint) scale, but accurate intra-tissue modeling must reflect complex intra-tissue interactions. Emerging multi-scale FE^2 methods (FE analyses augmented to derive the material behaviors from a distribution of finer scale FE analyses) are ideally suited to bridge the joint and intra-tissue scales, but have not yet been applied to multi-phase fibrous cartilage. We combined the theory of porous media (TPM) [2] and the FE^2-method [3] (i.e. the TPM^2 method) to solve 3-D, two-scale, non-linear, coupled, and time-dependent boundary value problems for materials with porous microstructures. We simulate, using our custom TPM^2 modeling framework implemented in FEBio, unconfined compression of cartilage explants. Within the superficial zone we employ new fibrous RVEs (with microcracks initiated) while the remaining cartilage (middle and deep zones) uses our existing custom FE framework. We perform: (1) sensitivity analysis on the modeling framework to quantify prediction sensitivity to input material parameters, (2) statistical analysis of material parameters to determine patient-dependent ranges. Finally, validation studies using cartilage explants to quantify propagation of microcracks ex vivo will confirm the predictive power of the simulation tools for ex vivo and in vivo studies [4]. The TPM^2 framework we established to understand how physical activity propagates microcracks in the collagen network of cartilage not only characterizes one of the earliest observable signs of deterioration related to osteoarthritis (OA), but also facilitate studies of other soft tissues and engineering materials.

Key Words: *Proximal Junction Failure, Finite Element Model, Adult Spine Deformity*

Purpose: Post-operative incidence of Proximal Junctional Failure (PJF) is observed by 61.7% in sagittal imbalance surgery [1]. In this study, Finite Element Model (FEM) is employed to find out the biomechanical etiology of PJF, highlighting effect of hardware density reduction.

Material and Methods: In this study, 42 patients (20 controls and 22 failures, EOS modality) are selected using inclusion criteria: age 50-75, Pelvic inclination> 20°, SVA> 5cm, PJF complications by the Hart criteria [2]. 3D spine tetrahedral meshes for non-operated images are generated using sterEOS software. To deploy the Statistical Shape Model (SSM), all 3D models are aligned and using Principal Component Analysis (PCA), principal modes of variation are obtained. Unstructured meshes of mean model is converted to the structured meshes using morphing techniques (TPS [3] for vertebras, and CPD [4] for IVDs). Then, dense deformation fields of SSM are applied to the mean structured model in order to have robust structured SSM. Two P-S control and failure models are regenerated including ligaments. Anisotropic hyper-elastic [5], linear elastic [6] and hypo-elastic [7] models are introduced for material properties of IVD, vertebra and ligaments, respectively. Eccentric load path in each vertebra centre is applied based on the weight of the patient [8]. Following FE simulation steps are used: 1-8hrs pre-swelling for IVDs, 2- 15mins to apply kinematic constraints (deformation fields between pre-op and post-op model) to correct the spine, 3- 1min for Instrument implantation and applying eccentric loads and 4- 3hrs to have steady-state conditions.

Results: Two P-S control and failure cases with hardware extended to T10 (UIV) are compared using FEM. Results revealed that the fibre maximum principal strain in IVD of UIV/UIV+1 in the failure case was 73.99% higher than in the control case (16.06% vs 9.23%). Also reducing 2 or 3 screw level below the UIV in the failure case could lead to get closer the mean fibre strain to the control. However, screw pull-out force was increased by 54% in case of hardware density reduction. But use of Cr-Co rod instead of TiAl4V could decrease pull-out forces by 50.5%.

Conclusions: Increasing fibre strains at UIV/UIV+1 may cause incremental disc degeneration in the etiology of PJK and leading to PJF. Also, screw density reduction reduces the chronic load at proximal IVD. However, such reduction has a limit because of screw pull-out. Trade-off analyses showed that removing 2 screws inferior the UIV with Cr-Co rod would be optimal by controlling the IVD strain and screw pull-out force. Effect of osteoporotic is interested for future works.

Key Words: *articular cartilage, inverse modelling, MRI, mechanical properties*

Osteoarthritis (OA) is a degenerative joint disease that is a leading cause of joint pain, disability, and health care costs worldwide. Diagnosing early-stage OA can be difficult due to a lack of validated outcome measures for individuals with early knee OA [1]. As most OA progresses from an initial injury to the superficial zone of cartilage and leads to biochemical and mechanical changes to the entire cartilage region, quantifying changes to cartilage material properties non-invasively in vivo is of substantial interest. MRI is unique among imaging tools as it can characterize tissues with high spatial detail, has a deep penetration depth, and can assess tissues noninvasively [1]. Recently, displacement encoded stimulated echo MRI (DENSE) has been used to calculate pixel level full field displacement maps of soft tissues under repetitive motion [2]. Leveraging this previous work, here we coupled DENSE MRI to displacement under applied loading MRI (dualMRI) to capture in vivo full field displacement and mechanical strain maps of the human knee while under load. We then present data for animal and human subjects combining this MRI method and a novel post-processing pipeline to acquire full-field cartilage displacements, and quantify *in vivo* cartilage stiffness and Poisson ratio.

An MRI-compatible loading apparatus that provides a varus-valgus load along the joint line of the knee was manufactured and validated. Following validation, the subject was imaged in a clinical MRI system (3T; Siemens Prismafit) using a cyclic loading regime (pneumatic, 25N load at foot, 1s load, 1s unload) to mimic a walking cadence. DENSE MRI was collected following achievement of quasi-steady-state response within the cartilage. Displacements for each pixel within the cartilage ROIs were determined and smoothed from phase data using custom software [2]. Material property characterization leveraging full-field displacement information was accomplished by combining both the virtual fields method (VFM) and a constrained FEBio-based optimization method to determine medial cartilage material properties. Ultimately, we hope this framework can provide a way forward to measure cartilage material properties in a clinical MRI setting and could potentially be extended to other load-bearing musculoskeletal tissues, including ligament and intervertebral disc.

Key Words: *Chondrocyte, Mechanotransduction, Network modelling, Osteoarthritis*

Osteoarthritis (OA) is a debilitating joint disease, characterized by articular cartilage degradation, local inflammation, and pain. An extensive range of *in vivo* and *in vitro* studies provide evidence that mechanical loads induce changes in chondrocyte gene expression, through a process known as mechanotransduction (MT). MT involves cascades of complex molecular interactions that, when triggered, convert physical signs to cellular response(s) that favor chondroprotection or cartilage destruction regarding the nature of loads. Systematic representations of those interactions can positively inform early strategies for OA management, and dynamic modelling allows semi-quantitative representations of the steady states (SS) of the system according to imposed initial conditions. In cell biology, we would compare long-term cell activity or phenotypes to these SS or attractors. To this end, a novel network-based model (NBM) in the form of a continuous dynamical system of CC activity is proposed.

The NBM incorporates key interactions from a corpus of 82 peer-reviewed articles from indexed journals. Then, an interactome is developed, consisting of a set of 115 nodes, i.e., cellular receptors, second messengers, transcription factors and proteins, related to each other through a specific topology of 256 directed edges. It is converted into a semi-quantitative mathematical model through a system of differential equations. To simulate a healthy SS of a CC including MT, the network is first stimulated with a physio-osmotic initial condition (TRPV4 and $(\alpha_5\beta_1$ activation). We further assess its capability to predict expected SS under inflammation and injurious loads (under static compression (ST) or high hydrostatic compression (HC) when PIEZO channels and patched receptor (PTCH) become activated). To validate the model, a qualitative validation (QV) is performed: we look for reported experiments and then we have counted how many of them can be replicated with our NBM.

Results show that under physio-osmotic conditions, an anabolic SS is reached with low levels of matrix metalloproteinases (MMPs), and high levels of structural proteins. Pro-inflammatory and HC perturbations lead to a significantly different (t-test, α=0.05) CC expression profile, as a catabolic SS is reached, reflected by fully expressed pro-inflammatory cytokines and MMPs. ST does not have such a strong influence on chondrocyte metabolism, but it reduces the presence of anabolic indicators. Regarding transcription factors, healthy markers (Sox9 and CITED 2) are fully expressed under physio-osmotic conditions, and reduced under inflammation, HC and ST. Contrary, NF-kB and Runx2, characteristic of an osteoarthritic CC, are activated by inflammation, HC, and ST. Concerning the QV, our NBM can replicate 88% of the experiments tested, but PTCH related experiments could not be reproduced, suggesting the need for a targeted enrichment of the NBM.

A regulatory network that maps intracellular signalling pathways of a CC was successfully developed. The model could predict expected MT and inflammation effects on general cell metabolism, revealing the potential of exploitation in OA.

Peripheral Nerve Injuries (PNIs), affect more than 1M people per year in Europe and the USA [1] with estimated costs above £1B in the USA alone. Paralysis and loss of sensation are common in severe PNIs, potentially leading to lifelong pain and loss of autonomy for patients. The current gold-standard treatment for large-gap PNIs use autografts to bridge between severed nerve stumps. Such a treatment requires additional surgeries, induces donor-site morbidity, and often yields underwhelming functional recovery [2].

Engineered Neural Tissue (EngNT) [3] is being developed to address these issues. EngNT constructs consist of cylindrical cellular hydrogels surrounded by a sheath of protective material. They aim at providing a supportive microenvironment to accelerate regeneration, whilst also enabling the careful spatial seeding of therapeutic cells and other regenerative factors.

Revascularisation of the injury site is an essential preliminary step of nerve repair, as microvessels are central in the delivery of nutrients and can serve as mechanical cues for neurite regrowth. To promote vascular regeneration, therapeutic cells seeded in EngNT release pro-angiogenic factors that act as chemical cues for the formation of new micro-vessels [4]. A key question is then to find which therapeutic cell type, density and spatial distribution will lead to the best revascularisation and be able to sustain long term regeneration.

We address this challenge by combining experiments with simulations. We develop a system of continuous, coupled, non-linear, diffusion-reaction equations that we parameterize using a dedicated set of in-vitro experiments. Doing so allows us to describe the interplay between the therapeutic cells and their microenvironment, including cell proliferation, nutrient consumption, and growth factor secretion. We then overlay this continuous description with a discrete model for vessel dynamics that includes a description of vessel growth, blood flow and molecular exchanges between the vasculature and the surrounding tissue. Coupling these two models allows us to reproduce the rich spatio-temporal dynamics between blood flow, angiogenic processes, oxygen delivery, growth factors and seeded cell population during the early stages of nerve repair.

Simulations are performed for different therapeutic cell types and for a range of cell-seeding densities and spatial distributions to explore the impact on angiogenesis and cell survival. Results predict the spatio-temporal distribution of cell density, oxygen, and growth factor throughout the microvasculature and EngNT. In particular, they indicate that seeding cells beyond a given threshold appears to be detrimental for long-term cell survival and vascular regeneration but that seeding them preferentially close to the nerve stumps can help sustain gradient of growth factors in the nerve repair construct. This computational-experimental approach therefore allows us to explore efficiently a wide variety of scenarios and identify new cell seeding strategies that may accelerate revascularisation of a repair construct and improve cell survival to be taken forward to in vivo experimental testing.

Novel Numerical and Analytical Techniques to Decouple Strain Energy Density in Materials with Poisson's Ratios Larger than 0.5

Key Words: *Biomechanics and Mechanobiology, Constitutive Models, Collagen Constructs*

Introduction: Strain energy density (SED) is a scalar measure of deformation that can be decoupled into hydrostatic and deviatoric parts. Hydrostatic energy controls volume changes while deviatoric energy controls shape changes (distortion). Decoupling SED is a common practice in biomechanics as the different parts are predictive of biomaterial damage, growth, and remodeling [1]. Moreover, uncoupled SED formulations are often used by finite element (FE) solvers to avoid numerical issues when modeling nearly- and fully-incompressible material behavior [2]. However, a notable limitation of existing hydrostatic formulations used for decoupling is that they are only suitable for modeling materials with a Poisson's ratio close to 0.5; yet, many biomaterials, including ligament, tendon, and collagen gels, exhibit Poisson's ratios that greatly exceed 0.5. Therefore, continuum constitutive models used to describe soft tissue behavior generally do not reflect the volumetric material behavior seen experimentally. A need thus exists to develop a constitutive framework to decouple energy in materials with large Poisson's ratios. Here we present numerical and analytical methods for decoupling SED in materials with Poisson's ratios larger than 0.5.

Methods: The numerical approach consisted of decoupling stress and strain tensors in small increments of areas and numerically integrating the areas under the stress-strain pairs. A custom MATLAB function was developed to implement this technique and was validated using three test cases with known answers: uniaxial tension (T), uniaxial compression (C), and biaxial tension-compression (CT). For the analytical approach, we introduced a new mathematical expression for hydrostatic energy that was paired with a deviatoric Mooney-Rivlin counterpart. Cauchy stress was derived based on this new decoupled SED formulation and implemented in MATLAB. This code optimized model parameters to experimental data using the Levenberg-Marquardt algorithm. The numerical and analytical methods were used to decouple SED on type-I collagen constructs that displayed large Poisson's ratios over 0.5 and were subjected to different loads (T, C, and CT).

Results: The numerical approach accurately calculated total SED in all three cases with less than 0.02% error, and calculated deviatoric and hydrostatic SED with less than 0.4% error. The analytical approach proved successful in modelling both small and large Poisson's ratios (all NRMSE's less than 0.2%). Moreover, these approaches revealed that collagen constructs have a significant difference in hydrostatic and deviatoric energies due to loading condition, as well as a negative hydrostatic energy in the large Poisson's ratio cases (T, CT), which supports the observation that soft tissue can lose fluid under loading [3].

Conclusion: The numerical and analytical methods developed in this study will help investigate whether hydrostatic and deviatoric energy can predict damage, growth, and remodeling in native and surrogate soft tissue. Importantly, the analytical framework has the potential to be implemented in FE solvers, which would open doors for more accurate modeling of volumetric behavior in a plethora of materials that display large Poisson's ratios.

Key Words: *tissue stiffening, fluid-structure interaction, brain injury*

The biomechanical properties of brain play an important role in understanding the basics of brain injury and development [1]. While many constitutive representations of healthy brain tissue are emerging [2-4], studies have found brain tissue becomes less stiff following damage [5, 6]. Besides stiffness change, injured brain tissue had significant morphological changes of cerebral vasculature [5]. We hypothesize the structure formed by this vasculature plays a central role in the mechanical response of brain tissue both before and after injury, and may be a determinant of an individual's injury susceptibility. To investigate structural changes of brain tissue after injury, we constructed a fluid-structure interaction (FSI) model of brain parenchyma and studied how vessel size, cerebral spinal fluid (CSF) flow velocity, and CSF flow mode could change the biomechanical properties of brain tissue. A representative volume element (RVE) was constructed for compression and shear testing. Results showed the vessel size, flow velocity, and flow mode could affect the shear modulus of RVE during shear, but not Young's modulus in compression. These highlight the importance of considering cerebral vasculature as a structure in predicting and analyzing the brain's response to mechanical loadings before and after injury.

An Electron Micrograph-Informed Axon Model Predicts Microstructural Failure Mechanisms

Lucy M. Wang*, Miriam B. Goodman and Ellen Kuhl

Stanford University, Stanford, CA, 94305, USA, lwang8/mbgoodman/ekuhl@stanford.edu

Key Words: *Axon, Damage, Heterogeneity*

In the United States, over 1.7 million people sustain a traumatic brain injury each year, and about 5.3 million people are currently living with a traumatic brain injury-related disability [1]. While the trauma itself occurs at the larger spatial scale of the whole head, the damage can be traced down to the smaller scale of individual axons within the brain. Computational head trauma models predict axon injury by applying a damage threshold to the calculated strains. However, the current roadblock in accurate predictive injury simulation is the selection of the appropriate safety level threshold for axonal failure.

Previous studies have used computational models of the axon cytoskeleton to investigate how axons fail under applied loading [2]. These past studies have all assumed an idealized geometry with regularly spaced microtubules and constant cross-sectional areas; however, serial section electron micrographs show that microtubules vary in number and length along neurites [3]. Since the weakest cross section initiates failure in this heterogeneous cytoskeletal structure, simulations using an idealized geometry tend to overestimate axon strength.

To address this issue, we used electron micrographs to build an axon model with more realistic microtubule structure and compared its mechanical response to that of an idealized geometry. Using serial section transmission electron micrographs taken of a 15-um long section of a *C. elegans* touch receptor neuron [3], we established a semiautomated procedure to identify microtubules in these images and reconstructed the structure of the microtubule bundle within the neurite. We then discretized the microtubule geometry using beam elements in Abaqus Standard and added truss elements to represent crosslinking proteins. For comparison, we also created idealized models with constant cross-sectional areas equal to the smallest, largest, and average areas found in the electron micrographs. In the realistic geometry, simulations of tensile loading revealed localized regions of high strain corresponding to the weaker cross sections with fewer microtubules. On the other hand, the idealized models exhibited a more uniform strain distribution along the axon. Furthermore, for the same overall axon strain, the peak crosslink stretch in the realistic geometry exceeded that of the idealized geometries by a factor of 1.5. For a given total axon strain, the heterogeneous distribution of deformation along the realistic geometry results in a higher risk of failure compared to the idealized geometry. Our study shows that idealized geometries overestimate axonal strength and underestimate the risk of axonal damage. We anticipate that our new axon model more accurately represents the microstructural failure mode of the axon under mechanical loading.

Key Words: *buckling, tissue remodelling, mechanical feedback, viscoelasticity, growth*

The mechanical and cellular processes that govern brain folding remain subjects of active research. Experimental data support a primary role of constrained cortical expansion, resulting in physical buckling, to drive the formation of gyri and sulci [1]. At the macroscopic level, computational models have provided useful exploration into the effects of mechanical feedback on developing brain morphology [2-3]. At the microscopic level, computational models require further development to understand the role of mechanical feedback on tissue-level changes.

Recently, we proposed a modelling framework in which biological behaviours, such as stress-dependent growth, may be assigned to specific cellular elements of brain tissue using volume fractions. By tracking changes in specific cellular constituents over time, this approach allows us to simulate tissue remodelling and infer microstructural changes that may result from mechanical factors. For example, by explicitly defining stress-dependent axon growth in terms of subcortical fiber volume fractions, models have predicted emergence of stereotyped anisotropy consistent with white matter organization [4]. In the present work, we extend this framework to consider microstructural remodelling in the cortex. We hypothesize that bending stresses resulting from cortical folding, such as increased compression in the superficial layers of sulci, contribute to differential patterns of cortical tissue anisotropy observed between gyri and sulci.

To probe cortical microstructure over the course of brain folding, we examined high resolution ex vivo diffusion tensor imaging from ferrets and rhesus macaques. We report stereotyped spatial patterns in diffusion anisotropy relative to gyri and sulci that are consistent with predictions of the computational model over the period of cortical folding. Thus, by simulating expected stress-dependent responses of specific tissue elements – including cell bodies, axons, dendrites, and extracellular matrix – in our model, we show that mechanical stresses resulting from folding may influence cortical microstructure in ways consistent with imaging and previously reported histological observations. As high-resolution diffusion tensor imaging becomes more common in research and clinical settings, these findings will provide context for the interpretation cortical FA maps as they relate to normal and abnormal brain development.

Key Words: *Human Brain, Viscoelasticity, Poroelasticity, Constitutive Modeling*

In recent years, it has been recognized that mechanics play an important role for human brain development, injury and disease [1]. Due to its extreme complexity, different experimental studies characterizing the mechanical behavior of brain tissue have reported seemingly contradictory results concerning the stiffness difference between gray and white matter tissue [1]. Computational models based on the theory of nonlinear continuum mechanics have proven to be a valuable tool to understand the physical mechanisms underlying the tissue response and can assist a profound analysis of associated experimental data. While the observed discrepancies in experimental data can be attributed to different testing techniques varying in time and length scales, also different boundary and drainage conditions in combination with the biphasic, poro-viscoelastic nature of brain tissue affect the results [2, 3].

In order to investigate the influence of viscous and porous contributions to the tissue response under different loading conditions, we model brain tissue as a poro-viscoelastic material using a numerical framework based on the Theory of Porous Media [2]. We explore the effects of various material parameters on the numerical response for three experimental loading modes: large-strain cyclic compression-tension, stress relaxation in compression and small strain flat-punch indentation. Thereby, we observe a strong coupling between viscous and porous effects, highly depending on the yet unquantified intrinsic permeability. Our simulations can explain why indentation experiments indicate that white matter is stiffer than gray matter, while large-strain compression tests show the opposite trend, and reveal the utmost importance of appropriate experimental data analysis.

Through our systematic numerical simulations, we find that the extremely complex and nonlinear tissue behavior evoked by its biphasic nature, cannot be captured by a single effective modulus from indentation experiments at relatively low strains nor by maximum stresses during large-strain loading. Such values do not necessarily represent the actual stiffness of the material and might change depending on the loading and boundary conditions. Since the fluid flow within and across the boundaries of the sample is key to the overall tissue response, experimental setups should be carefully designed in the future to avoid unwanted effects and measure the particular property relevant for a certain application.

Key Words: Machine Learning, Benchmark Datasets, Biomechanics, Spatial Heterogeneity

Using simulation to predict the mechanical behavior of heterogeneous materials has applications ranging from topology optimization to multi-scale structural analysis. However, full-fidelity simulation techniques such as Finite Element Analysis can be prohibitively computationally expensive when they are used to explore the massive input parameter space of heterogeneous materials. Therefore, there has been significant recent interest in machine learning-based models that, once trained, can predict mechanical behavior at a fraction of the computational cost. Over the past several years, research in this area has been focused mainly on predicting single Quantities of Interest (QoIs). However, there has recently been an increased interest in a more challenging problem: predicting full-field QoI (e.g., displacement/strain fields, damage fields) for mechanical problems. Due to the added complexity of full-field information, network architectures that perform well on single QoI problems may perform poorly in the full-field QoI problem setting. There are three components to the work presented in this talk. First, we introduce the Mechanical MNIST dataset designed to enable the investigation of full field QoI prediction. Second, we established strong baseline performance for predicting full-field QoI with MultiRes-WNet architecture. Third, we show results for creating generative models of spatially heterogeneous input patterns based on a limited number of examples to enhance a ML training dataset. In addition to presenting the results here, we have released our model implementations and datasets under open-source licenses. We anticipate that future researchers will directly use our model architecture on related datasets and potentially design models that exceed the baseline performance for predicting full-field QoI established in this paper.

Key Words: *Fetal Heart Biomechanics, Finite Element Modelling, Computational Fluid Dynamics, Fetal Heart Intervention, Congenital Heart Diseases, evolving HLHS*

Hypoplastic left heart syndrome (HLHS) is a severe congenital heart disease where the left heart and aorta are underdeveloped. Some HLHS developed due to fetal aortic stenosis and specific associated abnormalities during mid-gestation. Natural history of this condition showed that it led to progression to HLHS by birth in a majority of cases, thus the condition is known as evolving HLHS (eHLHS). In such patients, fetal aortic valvuloplasty could resolve abnormalities, induce better growth for some cardiac structures, and prevent progression to HLHS in some cases (66-72% biventricular births compared to natural history of 26-33%) [1,2]. Currently, little is known about the biomechanics consequences of the disease and intervention, although biomechanics stimuli are understood to guide cardiac development.

Here, we conduct image-based simulations to enable deeper understanding of eHLHS and intervention biomechanics, so as to inspire optimization of the intervention, and to enable better prediction of outcomes and more accurate patient selection, so as to improve efficacy. Both computational fluid dynamics (CFD) of blood flow mechanics, and finite element (FE) modelling of myocardial mechanics, based on 4D clinical echo images were conducted in conjunction with an age-scalable fetal Windkessel lumped parameter model.

CFD simulations demonstrated that eHLHS left ventricles (LVs) had a distinctively different flow dynamics, where mitral inflow occurred as a monophasic, narrowed and fast jet that transported a vortex ring directly to impinge on the apical region, leading to altered WSS spatial patterns. This was likely due to impaired mitral valve opening. Further, LV pressures, intraventricular pressure gradients, and energy losses were drastically higher than normal LVs. In post-interventional hearts, these abnormalities alleviated, but owing to aortic regurgitation from valvuloplasty injury, a narrow and fast aortic regurgitation jet that impinged onto the apical region dominated flow dynamics, retaining features of the altered WSS patterns.

FE simulations demonstrated that eHLHS hearts had drastically elevated LV and left atrial (LA) pressures and myocardial stresses and drastically reduced stroke volumes that depended on aortic stenosis severity, but these effects were moderated by mitral regurgitation. Myocardial hypertrophy often manifested that led to enhanced regurgitation severity, but contractility were likely reduced by cardiomyopathy. In the post-interventional LVs, de-pressurization of the LV could be attained to various extend, depending on extent that aortic stenosis was resolved. De-pressurization of the LA, however, depended further depended on the extent of aortic regurgitation, suggesting room for optimization on size of the valvuloplasty balloon. A workflow for quickly predicting acute outcomes from pre-interventional scan data was developed, which may improve on our currently poor ability to predict outcomes.

Key Words: *Body Position, Posture, Intraocular Pressure, Cerebrospinal Fluid Pressure, Optic Nerve Head, Finite Element, Ocular Biomechanics.*

The lamina cribrosa of the eye is continuously under intraocular pressure (IOP) and cerebrospinal fluid pressure (CSFP) from the anterior and posterior surfaces, respectively. A body position-dependent effect on the difference between IOP and CSFP may increase translaminar pressure (TLP), which that has been hypothesized as a possible risk factor in glaucoma pathogenesis. However, there have been few studies of the resultant stresses and strains within the lamina cribrosa trabeculae and interspersed neural tissues with TLP change. This study aimed to calculate the influence of postural change (sitting vs. supine) on the resultant stresses and strains in the optic nerve head, especially the lamina cribrosa beam and neural tissue, under simultaneously applied IOP and CSFP. Three eye-specific posterior microstructural finite element models were constructed, with circumferential, radial, and planar isotropic cable elements representing anisotropic collagen fibers embedded in the peripapillary sclera via a fully coupled, mesh-free, penalty-based beam-in-solid material-modeling algorithm. The FE models were then subjected to three different combinations of IOP and CSFP loading consistent with postural changes; results were then interpreted in relation to the postural role in the resultant optic nerve head deformations, stresses, and strains. The supine body position caused a larger tensile, compressive, and shear stresses and strains in the optic nerve head compared to the sitting position. IOP was the dominant (p<0.05) factor in the resultant stresses and strains in the laminar trabeculae and neural tissues compared to CSFP. IOP also was the dominant factor (p<0.05) driving deformations of the anterior and posterior scleral canal openings as well as anterior and posterior laminar insertions (~ 3 times larger than CSFP) while CSFP played a pivotal role in controlling the posterior laminar deformation. The cable elements representing the collagen fibers in the peripapillary sclera experienced a larger axial force in the supine compared to the sitting position, with IOP being the dominant factor compared to CSFP. Estimation of the resultant stresses and strains in the lamina cribrosa beams and neural tissues due to body posture could have practical implications for understanding the pathogenenic mechanisms of glaucoma and the ocular effects of idiopathic intracranial hypertension, as well as explaining visual impairment in astronauts in long-duration spaceflight.

Key Words: *Atrial fibrillation, stroke, machine learning, fibrosis*

Cardioembolic strokes are a leading cause of mortality in atrial fibrillation (AF), the most common arrhythmia with an estimated lifetime risk > 33%. During AF, impaired atrial wall motion creates stagnant regions where clots can form, typically in the left atrial appendage (LAA). Current tools to predict stroke risk in AF patients are not personalized and have modest accuracy. This paper outlines image-based computational approaches aiming to improve our mechanistic understanding of LAA thrombosis and predict cardioembolic stroke risk. First, we consider multi-physics LA simulations resolving the electrophysiology (EP), biomechanics, and flow physics. The simulations are informed by patient-specific MRI data, including late gadolinium-enhanced scans mapping fibrotic regions. Of note, atrial fibrosis is clinically linked to stroke risk but the underlying mechanisms remain elusive. In our EP model, fibrotic areas have altered action potential dynamics (slowed upstroke and prolonged refractoriness) and impaired conduction. Besides, we model mechanical fibrosis effects by locally increasing stiffness and reducing peak contractile active tension. These models are coupled to a computational fluid dynamics (CFD) solver to calculate blood flow, hemostasis metrics (e.g., residence time), and the evolution of clot promoting chemical species (e.g., thrombin). Our simulations suggest fibrosis dramatically increases thrombogenic risk in patients with tortuously shaped LAAs. Second, we consider the problem of inferring LAA hemodynamics, hemostasis metrics, and the concentration of clot promoting species from the dynamics of a passive scalar (contrast agent) in 4D CT image sequences. We implemented reduced-order models (ROMs) based on simplified advection-diffusion equations for the contrast agent, residence time, and chemical species, as well as physics informed neural networks (PINNs) representing the whole flow physics. The ground truth was obtained from CFD simulations. We found that, while advection-diffusion ROMs fail to capture the fine-scale features of residence time and chemical species, they accurately infer their average values. Due to their low computational cost, ROMs are well suited for extensive parametric runs to derive optimal imaging settings and contrast injection profiles. On the other hand, when contrast injection is properly tuned, PINNs fully infer LAA hemodynamics using each patient's 4D contrast agent concentration fields from CFD as training data. Overall, these studies illustrate how computational modeling can interface with medical imaging at various points along the fidelity vs. translatability axis to shed light on the determinants of atrial thrombosis.

Generation of Dynamic High-Order Patient-Specific Biomedical Meshes from Medical Images Using an Advancing Front Approach

Key Words: *High-order mesh generation, advancing front method, tetrahedral meshes, medical images, biomedical meshes, cardiac application*

Accurate biomedical simulations play an important role in aiding doctors with the diagnosis of and treatment of various diseases. High-order PDE solvers for biomedical simulations have recently attracted the interest of the computational science community since they yield accurate PDE solutions at a lower computational cost.

Most patient-specific geometric models and biomedical applications involve geometries containing curved surfaces. To represent the highly-curved geometries of the biomedical geometric models, high-order surface meshes with curved elements are used; these are paired with high-order volume meshes of the geometric domain's interior and high-order PDE solvers.

While various high-order mesh generation schemes have been developed, most of these methods require the geometric domain to be represented using a computer-aided design (CAD) model. However, CAD models are not readily available for biomedical applications. As such, the goal of our research is to develop a high-order mesh generation scheme that does not depend on use of a CAD geometry but instead generates high-order patient-specific meshes from medical images.

In this talk, we present our method for generating high-order patient-specific biomedical meshes from medical images [1]. To this end, low-order surface meshes are first obtained from the medical images. Next, these overrefined meshes are simplified and converted to high-order surface meshes. Our method then directly generates a high-order tetrahedral volume mesh using an advancing front approach. Finally, the mesh is smoothed to take advantage of the high-order degrees of freedom and to improve its quality.

We present several examples of high-order patient-specific biomedical meshes of soft tissues (e.g., liver and heart) and rigid tissues (e.g., bones) that our method generated from medical images. In addition, we present a dynamic cardiac application. For this application, the deep learning framework proposed in [2] was used to segment the cardiac chambers and estimate the cardiac motion from the cardiac cine magnetic resonance images.

Imaging Informed Computational Models of Skin

Key Words: *multiscale, multiphoton microscopy, microstructure, fiber networks, failure*

Skin is a complex, multilayered biomechanical structure, whose properties are dependent primarily on multiscale mechanical interactions that occur in the dermis. The dermis is a heterogeneous structure that largely consists of collagen, elastin, and proteoglycans. The composition and arrangement of these proteins, which can vary substantially with anatomic location, sex, ethnicity, age, and health, gives rise to its rich mechanical behavior. Although the biomechanics of skin has been studied for decades, new and interesting mechanical phenomena continue to emerge as new technologies become accessible. For example, the ability to observe both macroscale tissue deformation and microscale fiber-level restructuring has recently become possible[1]. These experiments use multiphoton microscopy during macroscale mechanical testing of mouse skin to acquire microscale quantitative data on collagen fiber density, organization, realignment, and kinematics. These experiments reveal that skin is not incompressible, that it exhibits large Poisson's ratios, and the fiber kinematics are non-affine with the macroscopic deformation of the tissue.

To better understand these data and their implications for explaining the mechanical behavior of skin, how the mechanical environment of skin changes with aging, and how aging leads to a higher susceptibility for tissue tearing, we have incorporated these data into a multiscale finite element model of the tissue. These imaging-informed mechanical models use volume averaging to connect a set of discrete microscale fiber networks to the macroscale mechanical behavior of the whole tissue. These models are able to capture many features of the complex behavior of the mouse skin observed experimentally. For example, the models were able to predict fiber restructuring within the sample gauge region, the force response, and the large decrease in volume observed with increasing stretch[2]. Models that were not informed with sample-specific details of the microstructure were not as accurate in their predictions.

We are now using these imaging-informed models to better understand the mechanism of tearing in skin as a function of age. To help localize the location of tissue failure for imaging purposes, dog bone shaped mouse skin samples were notched on one side of the center of the gauge region. The surrounding microstructure was imaged with multiphoton microscopy at each step of stretch. Models matching the sample geometry and boundary conditions were produced, and rules that break fibers that exceed a set stretch ratio were implemented. These models reveal an interesting pattern of restructuring around the notch that progresses laterally to the unnotched edge as the fibers fail. This behavior was also observed experimentally.

Key Words: *Medical Imaging, Artificial Intelligence, Computer Vision, Biomedical Applications*

Medical imaging has become an indispensable tool in medicine, enabling the diagnosis and treatment of previously debilitating diseases, by providing a patient-specific and patient-customized approach to therapy planning and guidance [1]. Medical imaging enables accurate and precise extraction of desired anatomical features, which, in turn, can be converted into virtual (and physical, thanks to 3D printing and rapid prototyping) replicas of the anatomy that can be used to model, simulate, plan and guide patient-customized therapies. Nevertheless, the pathway from medical imaging to biomedical modelling and simulation for biomedical applications entails the use of intelligent image computing and computer vision tools, many of which have been revolutionized by the latest development in artificial intelligence, which have been shows to achieve unmet performance, in terms of both accuracy, precision, and computational efficiency.

Our presentation as part of the *Imaging-informed Computational Modeling for Medicine* minisymposium will provide an overview of several tools and techniques that illustrate the power if integrating medical imaging, computer vision and artificial intelligence for several computational modelling and simulation applications in cardiology, image-guided robot-assisted interventions, and orthopaedic interventions. Specifically, we will present several deep-learning-based cardiac image segmentation and registration algorithms [2] that have enabled the creation of both static and dynamic surface and volume meshes of the heart [3] by capturing the geometry and deformation of cardiac features of interest from multi-dimensional medical imaging sequences, as well as their use for cardiac biomechanics simulations. Similarly, we will illustrate the performance of deep-learning-based image segmentation to automatically identify and label robotic instruments, in the effort to augment video sequences used for robot-assisted laparoscopic interventions [4]. Lastly, we will show how image-based characterization can be utilized to infer the biomechanical strength of bone to model and simulate optimal spine implant deployment.

In summary, this lecture will highlight several AI-enhanced computer vision tools that enable harvesting rich information from medical images to generate multi-dimensional 3D, 4D (3D + time) and 5D (4D + function) models of patient-specific anatomy or surgical instruments, to conduct simulations and provide new visualization to optimize computer-integrated diagnosis and therapy.

Key Words: *Pulmonary Biomechanics, Inverse Finite Element Analysis, Digital Image Correlation, Lung Mechanics, COVID-19*

Despite millions of premature deaths and billions of dollars in medical costs annually, pulmonary research remains nascent and extraordinarily underdeveloped, continuing to undermine scientific breakthroughs as witnessed during the COVID-19 pandemic. Computer simulations are key to inaugurating novel lung therapies and medical devices, but often lack physiological relevance due to the absence of experimental data. Here we capitalize on the linkage derived from the local deformation behaviour of the inflating whole lung organ when subjected to global inflation pressures and volumes using our custom-designed electromechanical ventilator and digital image correlation (DIC) unique interface [1,2] in order to produce the first experimentally informed three-dimensional inverse finite element analysis (IFEA) computational model [3]. Multiple hyperelastic continuum formulations are utilized to determine the optimal set of material parameters using both derivative-based and gradient-free algorithms to minimize the error between simulation and experiment. This reduced-order, image-based, pulmonary surface model (representing the contributions of the bronchi, parenchyma tissue, and visceral pleura) captures the heterogenous and anisotropic characteristics of the distending lung. The resulting innovative pulmonary macromechanics framework can be used to explore various medical ventilation modes, predict regional pulmonary force and stretch distributions, and be further adapted to assess diseased lung mechanics.

Key Words: Magnetic resonance imaging, Cardiac kinematics, Myofiber Strain, Cardiac modeling

Medical imaging provides a diversity of data for building patient-specific computational models of the heart. These models estimate performance variables that may not be measured directly (e.g., tissue stress and strain, hemodynamics, or electrical activity). Cardiac magnetic resonance imaging (MRI) can acquire time-resolved images that quantitatively encode myocardial displacements and microstructure. Herein, we summarize recent advances on how these data are acquired and fused using computational models to produce microstructurally anchored measures of patient-specific cardiac performance.

Cardiac MRI tagging and DENSE methods encode myocardial displacements in the magnitude and phase of the complex-valued MRI signal, respectively. The observed tagging motion or phase evolution can be decoded with conventional or machine-learning based image processing methods to produce a time-resolved material deformation mapping $\varphi(t)$ suitable for strain tensor ($\mathbf{E}$) calculations. $\mathbf{E}$ can be projected along a vector of interest ($\vec{v}$, e.g., circumferential or $\vec{c}$) to produce a specific strain component ($E_{vv} = \vec{v}\mathbf{E}\cdot\vec{v}$). Cardiac diffusion tensor imaging (cDTI) is an MRI technique that enables *in vivo* estimates of myocardial organization and produces a static pixel-wise estimate of the local diffusion tensor ($\mathbf{D}$). The primary eigenvector of $\mathbf{D}$ accords with the "myofiber" direction ($\vec{f}$). Hence, "myofiber" strain (E_{ff}) can be obtained using a suitable model that integrates $\mathbf{E}$ and $\mathbf{D}$. E_{ff} is microstructurally anchored and provides insight to cardiomyocyte performance, whereas E_{cc} is only a convenient geometric construct.

The most direct approach to estimate E_{ff} computes $\mathbf{E}$ by directly differentiating the deformation mapping measured with DENSE. Although efficient, differentiating the deformation mapping amplifies the experimental error. To overcome this problem, we estimate cardiac strains based on a kinematics model that contracts by imposing shortening along $\vec{f}$ measured from cDTI. By minimizing the difference between computed and measured motion, differentiating is avoided and subject-specific strains are then estimated.

The clinical adoption of these performance metrics requires validation of the methods used to compute them. Validation presents two challenges: 1) Evaluating image processing pipelines against a known ground truth; and 2) Measuring strain confidence intervals due to different processing pipelines and algorithms. In order to solve the first problem, we have developed a computational deforming heart model with known $\varphi(t)$. To solve the second challenge, we propose a cardiac kinematics benchmark problem to compare inter-method differences.

Ultimately, MRI informed models of cardiac performance may transform cardiac diagnosis by providing microstructurally anchored strains that can also be the input for simulations of cardiac mechanics, including the estimation of myocardial tissue properties and material law changes in disease.

Modeling Neuron Growth Using Isogeometric Collocation Based Phase Field Method

Key Words: *Neuron Growth Modeling, Phase Field, B-splines, Isogeometric Collocation*

We present a new computational framework of neuron growth based on the phase field method and develop an open-source software package called "NeuronGrowth_IGAcollocation". Neurons consist of a cell body, dendrites, and axons. Axons and dendrites are long processes extending from the cell body and enabling information transfer to and from other neurons. There is a high variation in neuron morphology based on their location and function, thus increasing the complexity in mathematical modeling of neuron growth. We propose a novel phase field model with isogeometric collocation to simulate different stages of neuron growth by considering the effect of tubulin [1]. The stages modeled include lamellipodia formation, initial neurite outgrowth, axon differentiation, and dendrite formation considering the effect of intracellular transport of tubulin on neurite outgrowth. Through comparison with experimental observations, we can demonstrate qualitatively and quantitatively similar reproduction of neuron morphologies at different stages of growth and allow extension towards the formation of neurite networks.

Key Words: Bone healing, Scaffold, Image-based simulation, Immersed Boundary Method.

Long bone fracture is usually stabilized with metal scaffolds like intramedullary implants. This technique implies two major surgeries, one for implanting the scaffold, and a second one for retiring the scaffold after the bone healing process has finished, which is mandatory according to practitioners and manufacturers due to possible long term negative effects [1].

We are involved in a project whose long term objective is to develop a numerical simulation tool for substituting the metallic implant by a bioabsorbable implant in order to avoid the second surgery. The first step of the process consist on simulating the bone healing process in order to obtain the daily mechanical requirements for the implant. Therefore, this work is focused on developing a numerical simulation tool for studding the patient-specific bone healing process. The technique used for that purpose is based on the Cartesian Grid Finite Element Method (cgFEM), successfully used in image-base simulation in the biomechanical context [2]. cgFEM allows to take into account the patient's bone medical image and bone remodelling process during the fracture healing process. In this case, the bone healing process is based on the use of fuzzy logic rules [3], showing a good correlation with experimental tests.

The numerical results provide information about the loads applied over the implant during the healing process, which is the starting point for the bioabsorbable implant design process.

Key Words: *Uncertainty, Clinical, Transcatheter, Repair, Predictive Modelling*

Clinically significant tricuspid regurgitation affects nearly 1.6 million Americans. Despite being termed a "public health crisis", few patients with functional tricuspid regurgitation (FTR) receive treatment. Moreover, 10-30% of patients that do receive treatment redevelop tricuspid regurgitation within a few years of surgery. We submit that these poor surgical outcomes are driven, in part, by an incomplete understanding of valve mechanics. Computer models built from patient-specific clinical data may be critical to this endeavour. However, building computer models from clinical data alone yields many challenges. Specifically, clinical imaging modalities such as ultrasound are unable to faithfully capture the intricate network of chordae tendineae that tether the valve leaflets. Additionally, tissue stiffnesses estimated through imaging-based inverse analyses are often orders of magnitude larger than those measured *in vitro*. Thus, we are faced with uncertainties in valve geometry and tissue material properties that limit our ability to accurately model the tricuspid valve. In this work, we examine the sensitivity of finite element models of the tricuspid valve to such uncertainties. To this end, we first obtain human tricuspid valves with FTR from hearts explanted after transplant surgery. Before the hearts are explanted, we record ultrasound images of the tricuspid valve in addition to valve hemodynamics. We then create an imaging-based finite element model of the regurgitant valve in absentia of any high-fidelity patient-specific data. Specifically, in this model we use an ultrasound-derived valve geometry, vary material properties based on values provided in existing literature, and use a topology optimization scheme to vary chordal configurations [1]. Through finite element simulations of the valve at end-systole, performed in Abaqus/Explicit, we determine the sensitivity of the imaging-based valve model to varied material properties and chordal configurations. Furthermore, to validate this model we use our previously established modelling framework to characterize the explanted tissue and build a high-fidelity finite element model of the same regurgitant tricuspid valve [2]. We then quantify the difference in predicted stresses between the high-fidelity and imaging-based valve models. Quantifying and analysing model sensitivities is essential to the advance of predictive modelling in biomedicine. In the future, predictive tricuspid valve models may be used for pre-surgical planning and medical device optimization which may help improve tricuspid valve repair outcomes.

Quantitative Stretch-Induced Collagen Fiber Recruitment and Microarchitecture Changes Using Instant Polarized Light Microscopy

Po-Yi Lee,[1] Bin Yang,[2] Ian A Sigal[1*]

[1] University of Pittsburgh, 203 Lothrop Street, Pittsburgh, PA 15213, ias6@pitt.edu
[2] Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15282, yangb1@duq.edu

Key Words: *polarized light microscopy, collagen, crimp, deformation, biomechanics*

Collagen architecture plays a central role in the biomechanics of soft tissues. While much has been learned about the macro and meso-scale mechanical properties of collagen, far less is known about the microstructural basis for tissue behavior, especially in tissues with complex microarchitecture. Polarized light microscopy (PLM) is a label-free imaging technique that has been widely used to visualize and characterize collagen architecture. However, quantitative PLM requires acquiring and analyzing multiple images, which complicates time-sensitive mechanical testing and microstructural analysis. We recently presented instant polarized light microscopy (IPOL) that allows label-free and direct visualization of collagen microstructure and orientation. IPOL leverages the full spatial resolution of the microscope-camera system, and its acquisition rate is only limited by camera speed. We demonstrate the IPOL-based tool by analyzing stretch-induced recruitment and deformation of tissues from the highly complex optic nerve head region.

Samples from the posterior pole of a sheep eye were prepared using sectioning techniques. The samples were then mounted on a custom micro-stretcher system and the stretching process was imaged with IPOL. Here we highlight three observations: First, the crimped collagen fibers in the peripapillary sclera (PPS) and lamina cribrosa (LC) beams straightened under stretch. At the initial state, the waviness (standard deviation of orientation) of crimp was significantly higher in the PPS (10.3°±2.6°) than in the LC (8.3°±2.5°). In addition, the uncrimping rate in the PPS (0.9±0.5) was significantly steeper than that in the LC (0.6±0.3°). This indicates PPS stiffening at a lower level of stretch, which could help protect the neural tissues in the LC from excessive mechanical insult. Second, we observed that stretch-induced PPS deformation was non-affine and inhomogeneous. Local deformations at the micro-scale varied greatly, even between adjacent collagen bundles. This indicates that resident cells may bear substantially different mechanical input even if only a few micrometers away. Third, at the micro-scale, the tissues do not behave in good accordance with some of the common assumptions of continuum mechanics. For instance, the tissues do not show conservation of volume or stretch-induced necking. Thus, to understand tissue and cell behavior it is necessary to develop more advanced models.

In conclusion, IPOL allows visualizing and quantifying collagen microarchitecture changes with stretch. This technique provides data that helps understand how the complex nonlinear properties of tissues arise from the collagen fiber microarchitecture. The experimental measures of collagen microarchitecture changes help drive fiber-based constitutive model formulations.

[5] Sankara Nethralaya Hospital, Chennai, India

Key Words: *Corneal stiffness; Keratoconus*

Purpose: To evaluate the regional corneal biomechanical deterioration with keratoconus (KC) progression as measured by the stress-strain maps (SSI)

Methods: In this retrospective record review, the preoperative of progressive KC cases that were submitted to corneal cross-linking (CXL) were evaluated. All cases were examined with Pentacam HR and the Corvis ST (Oculus, Wetzlar, Germany). Significant progression was based on the Pentacam's ABCD system. The SSI Maps were built on the first and last visits using numerical modelling based on the finite element method [1,2]. Through inverse analysis of patient-specific corneas the regional variation of mechanical stiffness across the corneal surface was determined.

Results: A total of 29 eyes were included. The cases presented the disease in different stages with maximum anterior curvature (Kmax) of 54.37 ± 4.55 D (44.5 – 64.4) and minimum thickness of 468.55 ± 27.74 μm (414 – 520). The mean age at the last exam before the CXL procedure was 20.1 ± 7.0 years (9 – 40). The mean time between the two examinations was 17.1 ± 17.1 months (1.4 – 58.4). The bIOP showed minimum non-significant alteration between the two exams (-0.08 ± 1.21 mmHg, range: -2.0 to 2.3, $p = 0.584$). The overall corneal stiffness as measured by SSI value in 8mm diameter presented slight but significant reduction from the first to the last exam (-0.02 ± 0.02, range: -0.09 to 0, $p < 0.001$). The regional reduction in stiffness was concentred in the area inside the cone. The SSI values inside the cone were significant lower in the last exam (-0.15 ± 0.09, range: -0.42 to -0.01, $p < 0.001$), while the SSI outside the cone presented minimum non-significant difference (0 ± 0.01, range: -0.04 to 0.01, $p = 0.999$).

Conclusions: It has been observed through the SSI maps that the regional deterioration in stiffness was concerted inside the cone area, while only mild non-significant alteration was observed outside the diseased area.

Key Words: *Swallowing Simulation, Four-dimensional CT, Muscle Anatomy, Muscle Activity*

The swallowing mechanics is still unclear. The swallowing is an intrinsic motion consisted of both transporting food bolus from the mouth to the esophagus and preventing from entering the trachea. Although the functional anatomy supposes 38 kinds of muscles activating the tissues, the mechanics between the tissue motion and the muscle activity and the food bolus flow has been not revealed. One of the breakthrough methods to reveal the mechanics is a computer simulation based on the medical images and the anatomical knowledge.
A computer simulation for swallowing needs both a tissue model and a food model. The tissue model consists of rigid models like the hyoid bone and elastic models like the tongue. The tissue model needed three steps to be created. The first step was to segment the tissues on images obtained from the four-dimensional Computed Tomography (4DCT) for swallowing. The second step was to adjust the muscles to the tissues. The third was to arrange particles to the muscles. The particles were calculation points for the simulation. The food model was created using its physical properties. The simulation method was a coupled analysis using the moving particle method which was one of the meshless methods. The muscle activity was obtained from the linear search method of the optimization calculation.
The result indicated that the muscle-driven swallowing simulation clarified all the tissue motions including the wave movement of the tongue, the pharyngeal constriction and elevation, the arytenoid movement and the opening of the upper esophagus. Moreover, the tissue motion changed the way as the muscle activity increased or decreased.
The muscle-driven swallowing simulation provided the precise soft tissue motion as well as the muscle activity which were unable for the 4DCT. The imaging-informed computer simulation will be able to reveal the whole mechanics on eating including mastication and swallowing.

Key Words: soft tissue, constitutive modeling, machine learning

Constitutive modeling of soft biological tissues has rapidly gained attention over the last 20 years. The microstructure and macroscopic mechanical properties of soft tissues like arteries are closely related. Histological anylsis, modern imaging, and biomechanical testing have deepend our understanding of these complex interrelations. However, predicting the mechanical properties from microstructural information yet remains an elusive goal.

To address this problem, we introduce a novel machine learning framework that combines advanced theoretical concepts with deep learning [1]. Using data from mechanical tests, histological analyses and advanced imaging, this architecture is trained to predict the nonlinear macroscopic mechanical properties of arterial tissue. The incorporation of substantial prior knowledge from continuum mechanics and materials theory enables our architecture to learn already from small amounts of data ($10^1 - 10^2$ samples) to predict the stress-strain curves of soft tissue with high accuracy ($R^2 > 0.9$). To the authors' best knowledge, this is the first time that macroscopic mechanical properties of soft tissue are predicted with such high accuracy from the tissue microstructure. Moreover, we demonstrate that our machine learning architecture is not limited to predictions but can also help to understand the mechanics of soft tissue. Using advanced concepts of explainable artificial intelligence, we demonstrate that it enables the automatic, systematic and largely unbiased quantification of the importance of different microstructural features for the macroscopic mechanical properties.

The machine learning framework we present bears promise to be transformative for our understanding of soft tissue mechanics and to provide new insights into the changes of soft tissues during aging and various diseases.

Key Words: *Soft Tissue, Continuum Damage Mechanics, Image-Based Model Validation*

Introduction. Meniscus tears are one of the most common orthopaedic injuries,[1] and surgeries to repair these tears are unable to effectively restore the native meniscus function. In order to help prevent meniscus tear injuries and improve surgical treatments, continuum damage mechanics (CDM) finite element (FE) models can be used to better understand the failure mechanisms and predict the loading conditions that cause tears to develop. However, the validation of these model formulations require comparisons to experimental data.[2] Digital image correlation (DIC) paired with high-speed video can be used to track tissue strains up to the moment of tissue rupture, enabling a precise comparison between model and experimental strains in the failure region.

Methods. Symmetric 1/8th dumbbell shaped coupons were built and analysed using FEBio studio (16144 elements).[3] Model parameters were tuned to stress-strain data from 10 monotonic tensile tests of human meniscus[4] using a transversely isotropic constitutive model. Damage evolution was modelled using a quintic polynomial with either von Mises stress criteria along the circumferential fibers, or 1st principle Lagrange strain criteria normal to them. The Lagrange strains and orientation of the tear region predicted by the model were compared to results from the DIC experiment.

Results. The selected model formulation provided average R^2 fits of 0.99 ± 0.01 for experimental data tested along the circumferential fiber network, and 0.97 ± 0.03 for data normal to the fibers. The concentration of maximum damage closely resembled the orientation of tissue ruptures from experimental data, with an oblique angle when loaded along the fiber axis, and a perpendicular one when loaded transversely. The model strains measured in this failure region were on average one-half to one-third those measured experimentally.

Conclusion. The excellent fits to experimental data, as well as the agreement between model and experiment regarding the tear orientation, suggest the selected constitutive model is appropriate to capture the anisotropic tensile failure behaviour of human meniscus. However, the inability of the FE model to correctly predict the high concentration of surface strain in the tear region indicates a potential limitation of CDM for modelling soft tissue failure. This study is the first to use full-field strain data to validate a damage model of meniscus tissue, and the results serve as an important advancement of failure theory for soft tissue and computational modelling of knee injury.

Key Words: Bone, Mircostructure, Brick-and-Mortar, Viscoelasticity

Many biological materials behave attractive properties and attract scientists to investigate ingredient and architecture of the materials. Among the natural materials, bone can be recognized as a biocomposite, which consists of mineral and protein, and features higher toughness than its individual ingredient. This characteristic gives a impetus to explore the bone further. The well-know theory for the mechanical behavior of bone with consideration of its microstructure, which is usually called ”brick-and-mortar“, is the tension-shear chain model [1] which can well capture the elastic modulus of bone [2]. The present study proposes a viscoelastic model of bone taking into account the brick-and-mortar microstructure and addresses the exact solutions of the viscoelastic model under stepwise, constant-rate, and cyclic loading paths. The comparison between the response of the viscoelastic model and experimental data of bone under monotonic loading shows an accepted result. The influence of mircostructure on the mechanical properties of the bone including the creep function, the relaxation function, the instantaneous modulus, the asymptotic modulus, the complex modulus, the storage modulus, the loss modulus as well as the loss tangent are investigated.

Key Words: Cortical Bone, Elastic-Plastic Material, Anisotropic Material, Tension Compression Asymmetry, Numerical Integration, Return-free integration.

Bone with the volume fraction of mineral more than 70 % is usually classified as the cortical bone (or so-called compact bone). The mechanical features of the cortical bone including the anisotropic and the pressure-sensitive response as wall as the yielding asymmetry in tension and compression and slight hardening have be widely observed. In the present study, we propose an elastoplastic material with an anisotropic elastic part, an associated flow rule with anisotropic-pressure-sensitive yield surface, a nonlinear isotropic hardening, and a nonlinear kinematic hardening to model the mechanical behavior of the cortical bone. In order to calculate the accurate simulation of the model, we consider the strain control cases as wall as the mixed control cases and develop the return-free integration of the model which is underpinned the internal symmetry of the Lie group $\mathrm{SO}(n,m,\mathbf{g})$ transformation, where the metric $\mathbf{g}$ is singular, and automatically updates the stress on the yield surface during plastic phase. The capability of the return-free integration is tested by the error analysis including consistency errors, average errors, and iso-errors. It shows the return-free integration of the model for the cortical bone is stable, acceptable, and reliable. Further, accurate simulation of the cortical bone based on the return-free integration enable us to investigate the mechanical behavior of the bone under different loading conditions.

Computational Insights into the Conformational Changes of Matrix Metalloproteinase in the presence of Nanoplastics

Key Words: *Extracellular Matrix, Nanoplastics, Molecular Dynamics Simulations*

Extracellular matrix degradation is a necessary process for numerous physiological and pathological events such as morphogenesis and wound healing, and matrix metalloproteinase-8 (MMP-8) is the major peptidase in the extracellular matrix that can catalyze several molecules, including aggrecan, gelatin, and collagen types I, II, III, VII, VIII, and X. The pollution of nanoplastics is of growing concern owing to their potential negative impacts on organisms. Nanoplastics are plastic particles with diameters less than 100 nm. Since nanoplastics are at least two orders smaller than eukaryotic cells, they are possible to penetrate into cells and influence organisms in molecular level. Moreover, nanoplastics have been found in the circulatory system of organisms. However, it is still unclear that how nanoplastics impact biological tissues after entering our body. Here we introduce a molecular dynamics approach to gain an insight into the effects of different nanoplastics on extracellular matrix degradation. It is found that different kinds of nanoplastics can cause different degrees of enzyme conformational changes, and they all influence the catalytic function of MMP-8 in different aspects. Our study shows the effects of nanoplastics on functional protein from an atomic-scale perspective, illuminating the urgent need for further understanding about the effects of various nanoplastics on other biological materials.

Molecular Dynamics Study on Mechanical Properties of Polyethylene Glycol / 2-Hydroxyethyl Methacrylate Organogel with Lithium Chloride

Yu-Cheng Lai[1*], Chia-Ching Chou[2]

[1] Institute of Applied Mechanics, National Taiwan University, R09543025@ntu.edu.tw
[2] Institute of Applied Mechanics, National Taiwan University, ccchou@iam.ntu.edu.tw

Key Words: *Organogel, Molecular Dynamics, Soft matters, Mechanical Properties*

Organogel[1] is a class of gel composed of organic solvent and cross-linking polymer network structure. The network structure within this material not only fixes organic solvent but also provides excellent mechanical stretching properties[1]. However, conventional organogel is unable to withstand high tensile stress. Recently, it has been found that by adding metal ions[2], the organogel can reach high failure stress and remain its high stretching property at the same time. While knowing that metal ion may increase crosslink density, the thorough mechanism is still unclear[2]. In our study, we focus on adding lithium chloride (LiCl) in polyethylene glycol (10-mer PEG) / 2-hydroxyethyl methacrylate (100-mer HEMA) organogel to study the strengthen mechanism.

Molecular dynamic simulation is used to study the difference between organogel and ionized organogel. We create two molecular models: pure PHEMA-PEG organogel and LiCl PHEMA-PEG organogel, and perform equilibrium simulation under NPT-ensemble with 300K and 1 atm. End-to-end distance, radius of gyration and persistence length of PHEMA and PEG are measured to understand the changes of polymers structure in two systems. Numbers of hydrogen bond and lithium-oxygen coordinate bond are analyzed. Finally, we perform tensile stress to study the modulus and structural change of the systems at the micro scale.

In LiCl PHEMA-PEG organogel system, we observe that end-to-end distance, radius of gyration and persistence length of PEG polymers decrease due to the effect of lithium ions. The number of hydrogen bond decreases from 974.69±71.35 to 770.61±38.62 while the number of lithium-oxygen coordinate bond between lithium and polymers dramatically increases, implying that the LiCl system has higher capability to withstand higher tensile stress. A higher density of crosslink of LiCl system implies that LiCl system is more stable and connected due to the coordinate bonds. Finally, from the tensile stress simulation, we obtain higher young modulus in LiCl than in pure PEG-PHEMA organogel.

In this research, we use molecular dynamic simulation to study the structural and mechanics difference of organogel and ionized organogel, and provide the explanation of the mechanism of the better mechanical behavior of the ionized organogel. From our result, it is shown that although lithium competes the oxygen in hydrogen bond, leading to a decrease in hydrogen bonds, the substituted lithium-oxygen coordinate bonds not only increase the stability, but also increase the failure stress of LiCl system. The findings from the atomistic modeling may help engineers to develop various functional organogel.

Yield surface evolution of trabecular bone

Li-Wei Liu[1], **Chang-Yun Yang**[2*]

[1] Department of Engineering Science, National Cheng Kung University, Tainan, Taiwan,
liweiliu@mail.ncku.edu.tw
[2] Department of Engineering Science, National Cheng Kung University, Tainan, Taiwan,
n96091415@gs.ncku.edu.tw

Key Words: Trabecular bone, Voronoi Honeycombs, Yield surface Evolution, Finite Element Method

The present study investigates the yield surface evolution of trabecular bone in an axial-shear stress space via the finite element analysis. A representative element or so-called unit cell of the trabecular bone is constructed with the microstructure of voronoi honeycombs and the initial and subsequenct yield surfaces of the representative element are probed. To model the mechanical property of trabecular bone, the relative density of voronoi honeycomb is 40 % and a bilinear elastoplastic material with asymmetric yield point in tension and compression is modelled in the finite element analysis. According to determination of yield point in the classical experiment of metal, the finite element analysis is conducted to simulate the uniaxial test and show the equivalent plastic strain of the voronoi honeycomb, then the proper determination of yield point in finite element simulations for the voronoi honeycombs is selected. The present study further extends the selected definition of yield point for 1D stress space to detect yield surfaces of the honeycomb in the axial-shear stress space via radial probing paths. Besides the initial yield surface of trabecular bone is detected, the bilinear pre-loading paths of displacement are applied to the voronoi honeycomb and the subsequent yield surfaces of trabecular bone are obtained. The observation on the finite element simulations shows the shape and the area of yield surface vary in different pre-loading paths of displacement.

Compressive Instabilities cause Densification Patterns in the Fibrous Extracellular Matrix, Facilitating Cell Migration and Invasion: Discrete Model Predictions

Key Words: *ECM Mechanics, Compression softening, Fiber compression instability, Fiber alignment, Intercellular communication*

Biological cells embedded in fibrous matrices actively remodel the surrounding network by inducing unique deformation patterns. These patterns include tracts of elevated densification and fiber alignment and have been shown to regulate significant cellular processes such us cell migration and invasion [1] and intercellular communication [2]. Understanding the mechanism underlying these phenomena is equivalent to characterising the mechanical properties of Extracellular Matrix (ECM) fibers.

Previous studies on fiber mechanics revealed unusual mechanical effects partly dictated by their hierarchical structure. These effects include multiple regimes of stress-strain responses under compression marked by transitions from hardening to softening [3,4]. Based on this evidence and moving beyond a previous continuum instability model [5] to include the crucial effects of discreteness, here we develop a discrete fiber network and implement various constitutive relations to explore fiber mechanical behavior under cell-induced loading. Our simulations reveal two distinct mechanisms of fiber and fiber group compressive instability due to buckling and identify matrix densification in the form of tethers connecting neighbouring cells and radial bands emanating around each cell, as a direct effect of these instabilities. Statistical inspection show enhanced alignment of tensed fibers along the direction of the densified zones while severely compressed fibres locate in the transverse direction, as experimentally observed. We show that both fiber alignment and matrix densification are prevented in the absence of elevated compression. Our models demonstrate that compression instability is a key player for both ample fiber alignment and matrix densification, rendering compression softening as the dominant nonlinear mechanism in fibrous ECM. This sets new insights in exploring fiber response to cell-induced deformations and its implications to intercellular biomechanical interaction.

Key Words: *Angioscopy, Flush, Computational Fluid Dynamics (CFD), Step injection, stenosis*

An angioscopy is an intravascular endoscopy device to visualize the colored interior of the blood vessel by delivering the endoscope to the arterial lesion using a catheter. Since the presence of blood flow usually blocks the view of the endoscopic camera, a transparent fluid flow, known as the flush flow, is needed to create a clear field of view between the camera and the arterial lesion, in order to obtain better quality images. In a previous study, we reported that using a step injection method, the visible area ratio of wall was 17-folds as large as that of using the conventional constant injection method; moreover, the optimised design of catheter also improved the visible area [1]. However, only a straight blood vessel was examined in the previous study, while the flushing behavior and effect of the step injection method on blood vessel in other geometries with more realistic feature remains unknown, which can be interesting and useful. Therefore, this study aims to evaluate the visibility of arterial walls in stenotic blood vessels using the step injection method.

Three stenotic models of coronary vascular wall were constructed using CAD software. The stenosis models represented a ball-shape, bilateral-shape, dome-shape, respectively. A step injection (180 mL/min *0.5 pulse) and the conventional injection (90 mL/min) flush was respectively applied to the inlet. ANSYS CFX 2020 R1 was adopted as a solver for the transient fluid flow simulation (1 pulse=1 sec). Then an integral of visible area ratio in a pulse (ARvar) was calculated for quantitative comparisons to the conventional injection.

Sections of the wall and the stenosis were observed from the camera viewpoint. The step injection created 1.4~7.0-folds higher ARvar than the conventional injection method in all models with different stenotic shapes. Especially, the bilateral-shape showed the highest ARvar, on the other hand, the ball-shape had the lowest ARvar. Compared to the straight artery, the effect of step injection is still higher than the conventional injection. However, the increase of visibility by step injection is smaller, especially the ball-shape.

In conclusion, the step injection to stenotic artery shows higher visibility of arterial wall compared to the conventional constant injection.

Key Words: *Mechanical Thrombectomy, Acute Ischemic Stroke, Vessel Tortuosity, Clot Stiffness*

Introduction: Mechanical thrombectomy with a stent retriever and/or aspiration catheter has been established as gold standard treatment for large vessel occlusion (LVO) in acute ischemic stroke (AIS). The first-pass effect, defined as successful complete or near-complete recanalization in the first attempt, has been associated with better clinical outcomes. Although high recanalization rates are reported with the advancement of devices and techniques, the rate of the first-pass effect is still approximately thirty percent. Therefore, it is imperative to understand the mechanisms underlying thrombectomy failure for early recanalization of LVO.

Several challenges in mechanical thrombectomy have been reported, such as tortuous anatomy of the vessels and stiff clots. However, the mechanisms for poor results in case of these challenges remained unknown. The aim of this study is to assess a new-generation aspiration system with hydro-separator technology that works regardless of clot size or composition.

The aim of this study is to examine the impact of vessel characteristics and clot stiffness on the performance of thrombectomy devices or techniques and to improve the efficacy and safety of stroke therapy.

Methods: We created artificial clot analogues with diverse stiffnesses and intracranial vascular silicone models with several tortuosities. The success rates of thrombectomy and vessel retraction force were evaluated in standard and challenging situations in realistic vascular models.

Results: Both the severity of vessel tortuosity and clot stiffness significantly affected the success rates of recanalization in simulated models. We observed that stent retrievers were stretched, collapsed in curved vessels, and lost clots in curved vessels. In addition, aspiration catheters ingested soft clots but not moderately stiff clots, whereas fragmentation of soft clots were observed with stent retrievers, although relatively stiff clots were well-integrated and removed. Aspiration catheters and stent retrievers with newer technology lead to significantly higher success rates than conventional devices.

Conclusions: Challenging situations were successfully created in 3D intracranial vessel models. This thrombectomy simulation system was useful to understand the underlying mechanisms of difficulties and to improve clinical decision-making in challenging situations.

Key Words: Virtual Patient Data, Cerebrovascular, Geometric Feature, *Multivariate Normal Distribution*

In recent years, methods to generate virtual patient database of artery geometry have attracted much attention due to the lack of sufficient database of medical images. B. Thamsen et al. generated a database of vascular geometries by the Statistical Shape Model (PCA-SSM) using Principal Component Analysis [1]. However, the basic concept of PCA-SSM does not contain the correlation of landmark points position [2]. Then, landmark points without the correlation can generate the unrealistic geometry on anatomical aspect. Recently, a method for generating virtual patient database assuming a multivariate normal distribution (MVND) method are proposed based on covariates such as age, weight, gender, and blood pressure [3]. This MVND method enables to generate a large set of variables with correlation. In this study, we introduce the method on generating a virtual cerebral artery database using the MVND method. The generated database was evaluated by the distributions of geometric features of the generated shape database.

The position of the 3D vascular centerline was extracted from MRA data. The centerline was divided evenly for each artery part: basilar artery (BA), left and right internal carotid arteries (ICA). We examined the number of equipartition 2 to 30 for BA and 2 to 100 for ICA. We assumed that the coordinates of x, y, and z at the equipartition points and the corresponding inner diameters d follows MVND. According to MVND, point groups and corresponding inner diameters were generated for 100 patients at each artery part. B-spline interpolation was performed with point groups to create a virtual patient database. The distributions of geometric features of the virtual patient database were compared with that of real patient database using length, tortuosity, curvature, and SOAM (sum of angle metric).

For BA and ICA, the distributions of length, tortuosity, and curvature of the virtual patient database were generally similar to those of the real patient database. However, in case three equipartition points were selected, the BA curvature distribution of the virtual patient database did not fit that of the real patient database. Therefore, virtual patient database using MVND may represent the real database with the complexity of cerebral arteries' bent if enough equipartition points number and B-spline interpolation are selected.

Virtual patient database of BA and ICA were generated using the MVND method. The distributions of the geometric features such as length, tortuosity, and curvature were similar to those of the real patient database, which suggests that this method is effective.

Key Words: *Myocardial infarction, ST elevation, Simulation, Solid angle*

Computer simulation provides a unique opportunity to examine the relationship between microscopic findings and clinical observations. We previously developed a multi-scale model of the human heart and torso, which can reproduce the surface ECG based on the ionic currents of cell models of electrophysiology(1) (2) (3). In this study, we applied this heart model to examine the ionic mechanism of ST elevation on an electrocardiogram that is a hallmark of acute transmural ischemia. However, the underlying mechanism remains unclear. We hypothesized that high ischemic sensitivities of epicardial adenosine triphosphate(ATP)-sensitive potassium (IK_{ATP}) and sodium (INa) currents play key roles in the genesis of ST elevation. Using a multi-scale heart simulation under moderately ischemic conditions, transmural heterogeneities of IK_{ATP} and INa created a transmural gradient, opposite to that observed in subendocardial injury, leading to ST elevation. These heterogeneities also contributed to the genesis of hyper-acute T waves under mildly ischemic conditions. By contrast, under severely ischemic conditions, although action potentials were suppressed transmurally, the potential gradient at the boundary between the ischemic and normal regions caused ST elevation without a contribution from transmural heterogeneity. Arrhythmias were observed under hyperkalemia with preserved ATP concentration. Slow conduction in the ischemic region may play a key role in the development of arrhythmias. These results provide the comprehensive understanding of the ionic mechanisms of ECG changes during transmural ischemia.

Key Words: *hemodynamic factors, wall shear stress, aneurysm*

An intracranial aneurysm (IA) is local ballooning of a cerebral artery. Historically, various hemodynamics indices have been proposed as etiologic factors of the development of intracranial aneurysms. However, which factor(s) is true remains controvertial. To sort out hemodynamic indices and shed light on the etiology of the disease, we are developing a numerical framework of the aneurysmal development, which accounted for an interactive linkage between hemodynamics, vascular wall mechanics and biological responses.

The aneurysmal evolution was simulated by cyclically repeating three steps; blood flow simulations, tissue remodelling and deformation. Given vascular geometry, blood flow was simulated to obtain hemodynamic indexes such as wall shear stress (WSS), and oscillatory shear index (OSI). The amount of vascular components such as elastin and collagen were then locally changed based on the magnitude of the hemodynamic indexes to mimic pathological tissue remodelling. Finally, the vascular geometry was updated by defomration analysis with internal pressureliziation at a physiological pressure. Cyclically repeatitive implementation of these steps provided the aneurysmal evolution associated with pathological tissue remodelling.

We illustrate its application to rat experiments where de novo aneurysms formed at the bifurcations created by end-to-side anastomoses with the bilateral common carotid arteries [1]. Blood flow simulations demonstrated high WSS, high WSS gradient (WSSG) at the apex of the anastomosis for flow impingement, and high OSI at the entire region of the anastomosis for recirculation. When high WSS and high WSSG were used combinedly as the driving factor, the aneurysm evolved at the apex. When OSI was adopted, the blood vessel bulged entirely near the anastomosis. The aneursms formed looked similar to the correponding rat experiments. These results suggest that a combination of high WSS and high WSSG, and high OSI are possible candidates of the driving factors of the aneurysm evolution.

Key Words: *fluid structure interaction, hemodynamics, biomechanics, computational modelling*

Objective: Bicuspid aortic valve (BAV) is the most common congenital cardiovascular defect (1-2% of all live births) characterized by the abnormal formation of two rather than three cusps. Approximately 50% of young adults with BAV, mostly fusion of the right and noncoronary (R/NC) cusps, develop premature calcification leading to aortic stenosis by age 35.[1] The etiology of premature calcification in BAV is poorly understood, but mechanical contributions are implicated. Computational studies of the mechanical stimuli along BAV cusps have focused on adult cohorts after onset of calcification. Our objective was to create fluid-structure interaction (FSI) simulations of young BAV patients to elucidate BAV-induced mechanical stimuli prior to calcification.

Methods: Magnetic resonance imaging of 23 y/o patients with R/NC BAV (n=1) and a healthy tri-cuspid aortic valve (TAV, n=1) were conducted after IRB approval. Aortic and coronary artery morphology were extracted using SimVascular (simvascular.github.io). Valve cusps were constructed in SolidWorks (Dassault Systems) using dimensions made patient-specific by scaling to sinus geometry.[2] Physiologic boundary conditions (BCs) were implemented including measured pressure at the aortic inlet, a lumped-parameter model of downstream physiology at the aortic outlet, and flow imposed at coronary artery outlets. Hyperelastic anisotropic material properties were applied using biaxial tensile results of human valve cusps from a 20 y/o.[3] FSI simulations were performed by coupling FlowVision (Capvidia) with Abaqus/Explicit (Dassault Systems). Three cases were conducted from the TAV patient including (1) TAV, (2) virtual R/NC fusion with the same BCs to elucidate the impact of BAV alone, and (3) R/NC fusion with tuned BCs mimicking physiologic compensation to BAV. A validation case (4) included fusion from the R/NC BAV patient. Quantification of mechanical stimuli such as wall shear stress (WSS) and von Mises stress were then extracted.

Results: Virtual fusion of the R/NC cusps in case 2 revealed reduced systemic pressure requiring tuning of BCs in case 3 to match clinical values. Both R/NC BAV cases showed similar alterations in mechanical stimuli, with differences due to tuning of BCs. The fibrosa/aortic surface of the BAV experiences higher WSS on the noncoronary cusp compared to the fused cusp during systole. High magnitude von Mises stress is also present near the fusion site, which is not present on TAV cusps.

Conclusions: To our knowledge these are the first FSI simulations to characterize the mechanical stimuli for a young adult with R/NC BAV prior to calcification. The methods allowed for robust assessment of mechanical stimuli on the valve cusps, and thus may ultimately allow us to further characterize the temporal mechanical changes in pediatric BAV patients leading up to calcification.

Key Words: *Functional Mitral Regurgitation, Mitral Valve Repair, Modeling and Simulation, Finite Element Method*

Mitral valve (MV) is the left-sided atrioventricular valve of the heart, composed of the mitral annulus, two leaflets, branched network of chordae, and two papillary muscles. During systole, it prevents the retrograde blood flow between left ventricle and left atrium. Computational modeling of the MV has recently emerged from an approach used to define the native mechanics of the valve and explore its physiology and pathology, to a powerful tool that allows to investigate the impact of novel treatment strategies for the diseased MV. Several new techniques to surgically repair or replace the diseased valve are now in development. Therefore, patient-specific computational simulations of the MV function before and after surgical repair can help surgeons to assess the interventional outcomes of such repair techniques and may be extremely useful in preclinical procedure planning.

We report a patient-specific 3D echo-derived MV modeling strategy, which can assist in procedure planning for the repair of functional mitral regurgitation (FMR), a disease that alters MV geometry resulting in inadequate closure and backward leakage of the valve. Such strategy was developed using echo images obtained in pigs with FMR. For each collected dataset, images were segmented and finite element model of the MV was reconstructed. FMR was induced by pre-straining the chordae. Annular contraction and movement of the papillary muscles were set as patient-specific kinematic boundary conditions. Physiologic transvalvular pressure was applied on the leaflets and explicit dynamic finite element simulation of the MV closure was performed.

The results of our simulations faithfully mimicked MV alterations inherent to FMR: excess leaflet tethering and reduced mobility, restricted motion of the papillary muscles, increased interpapillary distance, elevated leaflet stresses and chordal tension forces. In addition, validation of the modeling strategy was performed by comparing computational results and imaging data: for each dataset, a good agreement between simulated configuration of the MV leaflets and corresponding 3D echo images was observed.

Furthermore, the developed modeling strategy was tested to investigate the outcomes of various FMR repair techniques: undersized mitral annuloplasty, papillary muscle approximation, and implantation of MitraClip and Cardiac Leaflet Enhancer (CARLEN). In each case, we acquired realistic and reasonable simulation results, comparable to the results obtained on the bench in our lab **[1]**,**[2]**. Therefore, the presented modeling strategy may be used for preclinical procedure planning to assess the outcomes of different FMR repair techniques.

Key Words: *Statistical shape model, Hemodynamics, Deep learning, Data augmentation*

Deep learning has begun to be used for predicting hemodynamics instead of computational fluid dynamics (CFD) [1]. Deep learning is a data-hungry approach, yet obtaining enough number of medical data is difficult. Therefore, data augmentation plays an important role to maintain the accuracy of deep learning prediction. For 3D geometry of aorta, statistical shape model (SSM) is often used to increase the number of training data. SSM generates the virtual patient geometry using principal component analysis (PCA) of several real patient's geometry. However, in general, SSM has difficulty in maintaining the continuity of the geometry and controlling the geometry parameters. For these reasons, SSM is difficult to be applied to the complex artery shapes. In the study of artery SSM, only the aorta is mainly used [2]. In our study, we propose a new SSM approach for human's aorta with carotid artery parts.

The centerline and radius of each point was extracted from the 4 real patient's aorta and carotid artery STL data. The centerline of the aorta was divided into 30 equal parts. The carotid artery was also divided in the same span as the aorta. Virtual patient data was generated as a set of centerline for each artery part by SSM. Then, 3D surface was reconstructed around the centerlines. To maintain the continuity of the model, we used the relative coordinates of the centerline instead of the absolute coordinates. In the relative coordinates, the previous point was used as a reference. The vector from the previous point to the next point was represented as a coordinate value. To evaluate the continuity of the model, the angle between each point and the front and back points was calculated.

Our SSM successfully constructs both parts of aorta and carotid arteries. Since SSM was constructed independently for each artery part, deformation can be performed respectively. The average angle of the aorta part is 2.52 ± 0.52 rad in absolute coordinates. On the other hand, the average angle is 2.91 ± 0.18 rad in relative coordinates. From the value of the SD, there is a larger angle variation in the absolute coordinates. This result shows that SSM using relative coordinates maintains the countinuity of the centerline SSM.

Our developed SSM can add deformation to complex branches between aorta-carotid artery with maintaining continuity.

Key Words: *Hyperelasticity, Finite Element Model, Muscle Contraction, Shape Memory Polymers*

We develop a unified approach to mathematical modelling of muscles and polymeric 3D printed bionic actuators. It consists in three-dimensional finite element thermoelectromechanical modelling based on active strain approach. In the underlying mathematical model, the deformation gradient tensor is decomposed into passive and active parts. Passive response is modelled by a transversely isotropic nonlinear hyperelastic material model whereas the active behaviour is characterized by contraction associated with actin–myosin interaction in the case of muscles [1] or thermal activation in the case of polymers exhibiting shape memory (SM) effect [2].

In order to capture the SM effect, multi-branch models are often applied by considering the thermomechanical phase transition as the temperature crosses glass-transition temperature Tg. This type of models are time- and temperature-dependent and applicable for 4D printing with the fourth dimension referring to time [3]. 3D-printed SM polymeric objects demonstrate large recoverable deformations to the initial state being heated above Tg. Such programmable materials are often called “smart” due to their capability to change actively geometric configuration and widely used for medical, civil and aerospace applications.

Current research involves constitutive models for skeletal muscles and shape memory polymers revealing electromechanical and thermomechanical behavior respectively, three-dimensional finite-element implementation and the corresponding experimental investigations of SM behavior of 3D-printed polymeric objects.

Key Words: *Muscle Atrophy, Intervertebral Disc Loading, Musculoskeletal Modelling*

Long duration spaceflight has been reported to elevate the rates of back pain and spinal diseases in astronauts. It has been observed that long-term microgravity exposure causes significant atrophy of lumbar spinal muscles [1]. Studies have reported associations between muscle atrophy and spinal diseases such as lower back pain and disc herniation. However, the biomechanical mechanisms underneath such associations are not clear. This study is aimed at exploring the influence of lumbar muscle atrophy on the loading of human lumbar intervertebral discs with a multibody modelling approach.

The effects of lumbar muscle atrophy on disc loadings were studied using a full body musculoskeletal model developed with the AnyBody Modeling system (AnyBody Technology,V7.3, Denmark)[2]. Specifically, the lumbar intervertebral discs were modelled as 6 degrees of freedom joints with linear elastic properties [3]. The swelling effects of the discs were considered, with swelling pressure dependent on the fixed charge density of the disc. The water content and fixed charge density are tissue deformation dependent. The ligaments were considered as non-linear elastic elements. The maximum strength of the muscles was dependent on muscle functional cross-sectional area (FCSA). In this study, atrophy of lumbar muscles was modelled with reduction of muscle FCSAs. Two levels of FCSA decrease, namely, 20% and 40% decrease, of lumbar muscle groups (multifidus, erector spinae, quadratus lumborum, psoas major, transversus abdominis, obliquus internus, and obliquus Externus) under eight daily postures (lying supine, slouched seating, straight seating, relaxed standing, standing bent forward, standing lifting a 20 kg weight close to chest, standing lifting 20 kg with spine flexed 45^{o}, and standing lifting 20 kg with arms stretched) were studied.

Our predicted loads on the lumbar discs under eight daily postures without muscle atrophy were consistent with experimental data [2]. The predicted compressive and shear forces on the lumbar intervertebral discs showed no significant change with lumbar muscle atrophy in lying and sitting postures. However, they increased in the standing and standing flexed postures with or without carrying weight. The degree of increase was larger at a higher level of muscle atrophy. This study is important for understanding the biomechanical mechanisms of how lumbar muscle atrophy may affect the lumbar intervertebral disc health.

Machine Learning to improve Musculoskeletal Biomechanics Analysis

Eva Dorschky[1], Markus Gambietz[1], Marlies Nitschke[1], Anne Koelewijn[1*]

[1] Machine Learning and Data Analytics Lab, Department Artificial Intelligence in Biomedical Engineering, Friedrich-Alexander-Universität Erlangen-Nürnberg, Carl-Thiersch-Str. 2b, 91052 Erlangen, Germany, anne.koelewijn@fau.de

Key Words: *Machine Learning, Neural Control, Personalization, Movement analysis*

We are currently researching the application of musculoskeletal (MSK) models for new goals, such as sports performance monitoring and prosthesis and exoskeleton design and optimization. These applications require advanced MSK models, for example personalized models, models that include a model of the neural control system, or real-time processing of measurements in the natural environment. MSK model personalization and model extensions are challenging, since invasive and/or expensive measurements are required, while real-time data processing, especially of measurement in the natural environment, requires new biomechanical data processing methods.

Machine learning (ML) is a promising technique to advance MSK models to achieve our goals. ML models could provide real-time data processing, while ML can also be used to extract more information from existing measurement data to allow for model personalization or extension. The application of ML has become possible recently due to the increasing availability of large datasets containing biomechanical movement data. Some laboratories have databases containing hundreds or thousands of measurements [1], while recent developments also allow for fast generation of movement simulations [2], which can artificially increase dataset size.

We currently investigate if and how combining MSK models and ML can advance MSK models towards our goals of sports performance monitoring and prosthesis and exoskeleton design and optimization. Therefore, we will present (preliminary) results and highlight future approaches where ML techniques are used to improve MSK model outcomes.

(1) **Machine learning for real-time biomechanical analysis in-the-wild.** We trained neural networks to output kinetics and kinematics from inertial sensor data, to develop an approach for real-time processing of biomechanical data recorded in the natural environment. We used gait simulations to increase data-set size and improve network accuracy [3].
(2) **Neural networks for gait control.** Currently, neural control models require a pre-defined model shape, e.g. a reflex model [4], which could bias their outcome. We are developing an approach to combine musculoskeletal simulations with neural network training to train unbiased controllers to replicate human control.
(3) **Personalized musculoskeletal models.** Gait measurements of each person are unique. Therefore, we will explore if we can train a neural network to personalize MSK models from gait measurements, and use these neural networks to investigate individual anthropometrics.

Towards in vivo Passive and Active Force Estimation of Skeletal Muscle using Shear Wave Elastography

Manuela Zimmer[1*], Benedict Kleiser[2], Justus Marquetand[2], Filiz Ates[1]

[1] University of Stuttgart, Pfaffenwaldring 27, 70569 Stuttgart, Germany, manuela.zimmer@isd.uni-stuttgart.de, filiz.ates@isd.uni-stuttgart.de

Key Words: *Shear wave elastography, Biceps Brachii, Force Estimation, Electromyography*

Modelling and simulation of skeletal muscles are essential to better understand musculoskeletal diseases and improve treatment strategies. However model validation for in vivo muscular structures is not straight-forward. Muscle forces measured directly at the respective tendons intra-operatively can be used for validation [e.g. 1]. Though such an invasive intervention is not feasible for many scenarios in particular for healthy muscles. Surface electromyography (sEMG) is widely used for active muscle characterization, but it does not represent the passive state of muscles. Previously, muscle stiffness deduced from shear wave elastography (SWE) was shown to represent muscle mechanics [e.g. 2]. The objective of the present study was to investigate the use of a SWE approach in understanding active and passive force production of skeletal muscles in vivo by characterizing the biceps brachii muscle (BB) in relation to elbow joint position and function. We hypothesized that changes in mechanical properties of the BB can be detected both in passive state and during isometric ramp contractions at different activity levels for various muscle lengths. Therefore, we investigated whether SWE is a better method in revealing individual muscle mechanics in relation to joint function which would help improve existing muscle models.

SWE, sEMG of BB, and isometric elbow torque measurements were performed on 10 healthy volunteers (5 males, 27 ± 4.92 years, 72.7 ± 10.5 kg, 176.2 ± 5.03 cm) after they gave written consent to participate. A passive trial, maximum voluntary contractions (MVC) and isometric ramp contractions (up to 25%, 50%, 75% of MVC torque) were performed for five elbow angles (60°, 90°, 120°, 150°, and 180°).

At passive state, elastic modulus of BB deduced from SWE significantly changed between flexed and extended elbow angles (e.g. between 60°/90° to 180°, $p<0.02$) but no significant differences were observed for sEMG root-mean squared amplitude (RMS) ($p<0.05$), supporting our hypothesis of SWE but not sEMG being able to characterize passive mechanical muscle properties. During ramp contractions, we found that normalized sEMG represents muscle activity ($R^2>0.75$) but cannot detect contribution of BB to elbow function at higher lengths. In contrast to flexed positions, elastic modulus vs normalized elbow torque did not show a linear relationship at extended positions. We conclude that SWE providing more realistic results can be developed as an index of muscle force. If validated with experiments [e.g. 1], SWE findings can be used to improve muscle models and simulate the effects of e.g. exercise, neuromuscular conditions, or treatments.

Understanding in vivo Skeletal Muscle Mechanics within Connective Tissue Matrix: An Intraoperative Approach

Filiz Ates[1]

[1] University of Stuttgart, Pfaffenwaldring 27, 70569 Stuttgart, Germany
filiz.ates@isd.uni-stuttgart.de

Key Words: *muscle force, joint function, cerebral palsy, neurologic and non-neurologic foot deformities*

For a better understanding of human locomotion, it is necessary to relate individual muscle function to the joints it crosses. More importantly, it is essential to assess the mechanical behavior of skeletal muscles not only in isolation but also with respect to the connective tissue matrix that they are embedded in. Previously, we developed an intraoperative approach based on measuring muscle forces through its respective tendon using buckle force transducers during orthopedic surgeries [e.g. 1-3]. Using this method, the mechanical behavior of healthy and diseased hamstring muscles was investigated in relation to knee joint angle. We found that even though children were taken to surgery due to a severe knee joint limitation, the data collected from spastic hamstrings indicated no abnormal mechanical characteristics if the muscles are activated alone [1]. Interestingly, when activated together with antagonistic and/or synergistic muscles, systematic and significant increases of the muscle force were observed [2, 3]. These indicated the relevance of muscular interactions through connective tissues on joint restriction in neuromuscular diseases.

In the present work, force production capacities of muscles crossing the ankle joint are studied directly at various ankle positions. The experiments are performed in Universitätsklinikum Heidelberg, Germany after patients give written consent. The isometric forces of supramaximally stimulated triceps surae, tibialis anterior, and tibialis posterior muscles are collected at available ankle flexion and extension angles from patients with cerebral palsy, neurofibromatosis as well as non-neurologic foot deformities. Histological examinations performed on biopsied samples to quantify intramuscular connective tissue content are matched with the in vivo muscle function and state of the disease. The findings of the present study will reveal the effectiveness of surgeries performed in order to improve foot deformities such as tibialis anterior or tibialis posterior tendon transfers where not only the tendons but also the fascial connections are disrupted. The results will be discussed in terms of improving the existing modeling and simulation approaches that aim to guide surgical decision making and treatment strategies. In combination with advanced marker-based motion tracking and ultrasound imaging as well as MRI scans obtained before and after surgery, a 3D continuum-mechanical model based on unique constitutive laws will be possible.

Whiplash Simulation: How Muscle Modelling and Movement Interact

Matthew Millard[1]*, Tobias Siebert[1], Norman Stutzig[1] and Jörg Fehr[2]

[1] Institute of Sport Science, University of Stuttgart, Allmandring 28, 70569 Stuttgart, Germany, (tobias.siebert@inspo.uni-stuttgart.de)

Key Words: muscle, eccentric contraction, impedance, titin, crash simulation

Whiplash injury and associated disorders are costly to society and individuals. Accurate simulations of neck movement during car accidents are needed to assess the risk of whiplash injury. Existing simulations indicate that Hill-type muscle models are too compliant, and as a result, predict more neck movement than is observed during *in-vivo* experiments.

Simulating head and neck movement is challenging because many of the neck muscles operate on the descending limb of the force-length curve [1], a region that Hill-type models inaccurately capture. Hill-type muscle models have negative stiffness on the descending limb of the force-length curve and so develop less force the more they are lengthened [2]. Biological muscle, in contrast, can develop large transient forces during active lengthening and sustain large forces when aggressively lengthened [3].

Recently, a muscle model has been developed [4] that mimics the active impedance of muscle in the short range and can capture the large forces generated during extreme lengthening. In this work, we will compare the accuracy of simulated neck movements, using both a Hill-type model and the model of Millard et al. [4], to the *in-vivo* neck movement. If successful, the improved accuracy of our simulations will make it possible to predict and help prevent neck injury.

Key Words: *Dental Biomechanics, Cleft Palate, Finite element simulation*

Cleft palate patients can significantly benefit from treatment based on alveolar graft deposition, a procedure with high success rate in young people. When treatment is delayed, after 12 years of age, the success of the procedure drastically decreases [1]. Probable causes for this decrease in success is the absence of both the child's growth stresses in the maxilla as well as of the eruption of the second dentition, which occurs up to the age of 12 [2]. This study aims to use numerical simulation to analyse the effect of a distractor to enhance the results of alveolar graft treatment in late cleft palate patients. The process of expanding the maxilla simultaneously with graft deposition would ideally induce stresses in the bone graft region, leading to osteoblast activation and bone growth.

After standard cleft palate treatment without distraction, cone-beam computed tomography (CBCT) images were compared to a numerical simulation. The linear elastic model with non-homogeneous elastic moduli for the bone was subjected to a loading simulating palatal expansion using the distractor in ANSYS. The patient's graft density data were correlated to the bone elastic modulus to simulate the clinical conditions of maxillary expansion. Graft density data were acquired from CBCT images and loaded into automated reconstruction commercial software Dolphin 3D and the geometric model was constructed in MIMICS.

The comparison of MEF stress distribution with the clinical bone resorption images of the CBCT for a cleft palate adult patient 60 days after surgery showed that low stress levels in the middle of the graft coincided with graft reabsorption areas as expected. As for the simulation of the use of the distractor simultaneously with the graft application produced evidence that the stress distribution corresponds to a situation that can be related to a positive stimulus to bone growth and graft consolidation. Further clinical research is needed to validate these results, and numerical simulation has shown its potential for guiding alternatives in cleft palate treatment.

Computational cardiac electromechanics: the role of mechano-electric feedback and its arrhythmogenic effects in three-dimensional ventricular models

Yongjae Lee[1], Barış Cansız[1] and Michael Kaliske[1*]

[1*] Institute for Structural Analysis, Technische Universität Dresden, 01062 Dresden, Germany, michael.kaliske@tu-dresden.de

Key Words: Cardiac electromechanics; Mechano-electric feedback; Stretch-activated channels; Commotio cordis; Precordial thump; Premature ventricular contraction

The role of the human heart is to circulate the blood in order to provide every cell with vital nutritions via the cardiovascular system. Any irregularities might lead to the loss of life quality, and even sudden death. Therefore, stable circulation in the cardiovascular system is important. The steady and healthy circulation can be performed by the well-balanced harmonization between Excitation Contraction Coupling (ECC) and Mechano-electric feedback (MEF). In contrast to ECC, by which electrical activation of cardiac cells triggers the mechanical contraction of the heart, is well characterized, less is studied about the cellular mechanisms of MEF, where mechanical alterations in the heart influence back cardiac electrical activity.

The goal of this study is to investigate the role of MEF in healthy cardiac cycles and in cardiac arrhythmia using human ventricular models. The effect of MEF is manifested by stretch-activated channels (SACs). The numerical formulation of SACs in terms of the fibre stretch of the myocardium is embedded in the modified Hill model that describes the myocardium as an electro-visco-active material [1]. In addition to the existing models of SACs in terms of the stretch along fibre direction [2], we propose models of SACs formulated in terms of the rate of stretch along fibre direction and the stretch along sheet direction. The influences of the three different models for SACs and different material properties on the regular cycles are analyzed by using the electrocardiogram and volume-time curves, and show that the each model of SACs leads to regionally varying reactions on the heart model. Moreover, we simulate 'commotio cordis' and 'precordial thump' and demonstrate that MEF take a vital role in fibrillation and defibrillation without the structural impairment in the heart. Furthermore, we study the role of MEF in premature ventricular contraction when the heart is hemodynamically disturbed.

Key Words: Biomechanics, Constitutive Modeling, Viscoelasticity, Fractional Derivatives, Cardiovascular Tissues

While experimental evidence shows that the mechanical response of most tissues is viscoelasticity, current biomechanical models used in computational studies often assume only hyperelasticity. Fractional viscoelastic constitutive models have been successfully used in literature to capture the material response. However, the translation of these models into computational platforms remains limited due to a computational cost that is $O(N_T^2)$ and a storage cost that is $O(N_T)$ in order to store and integrate historical data. We developed a novel numerical approximation to the Caputo derivative which exploits a recurrence relation to give a computational cost that is $O(N)$ and a storage cost that is fixed over time [1]. We used this approach to extend the conventional analysis of residual stress in aortic soft tissues by considering the effects of viscoelasticity [2]. A substantial portion viscoelastic tissue is necessary to capture the long-term dynamics of the residual stress experiment. In addition, the results show that conventional estimates of residual stress are over-estimated a factor of 2 and that viscoelasticity is necessary to accurately estimate residual strain. Using this approach, we developed a fractional viscoelastic model for myocardium that improves the quality of fit compared to current models in the literature [3]. This allows us to develop an inverse modeling approach, incorporating full 3D fiber architectures, for the estimation of the viscoelastic properties of myocardium from tri-axial mechanical experiments. These results demonstrates that fractional viscoelasticity has enormous potential for facilitating the analysis of viscoelastic properties of soft biological tissues in computational problems.

Modeling the two-pathway contraction of smooth muscle in arterial walls

Klemens Uhlmann[1] **and Daniel Balzani**[2]

[1/2] Chair of Continuum Mechanics, Ruhr University Bochum, Universitätsstraße 150, 44801 Bochum,
klemens.uhlmann@rub.de, daniel.balzani@rub.de

Key Words: Biomechanics, Arterial Wall, Smooth Muscle Cells, Active Response

Patient-specific numerical simulations are considered a promising toolbox for the improvement of clinical practice by allowing the detailed numerical analysis of atherosclerotic arteries with respect to e.g., efficiency and influence of antihypertensive drugs or plaque development and rupture. One important contributor influencing the resulting mechanical fields is the active contraction of smooth muscle which is in turn influenced by the deformations due to a change of the intravascular pressure. During the stretch of smooth muscles cells (SMCs), two different mechanisms are triggered: the calcium-dependent and the calcium-independent contraction [1]. For the calcium-dependent contraction mechanism, the stretch of the SMCs leads to an inlet of calcium ions through various different pathways and activates the myosin light chain kinase (MLCK) leading to the contraction. For the calcium-independent contraction mechanism, stretch-dependent receptors of the cell membrane stimulate an intracellular reaction chain which leads to an inhibition of the antagonist of MLCK, the myosin light chain phosphatase (MLCP). While the calcium concentration can change over a rather small time frame, the inhibition of MLCP lasts much longer. We present a chemo-mechanical model which describes both, the calcium-dependent and the calcium-independent contraction of SMCs. As a basis for the mechanical description of the contractile units, the model by Murtada et al. [2] making use of the chemical model of Hai and Murphy [3] is considered. A new set of equations is presented to describe the stretch-dependent calcium inflow and the inhibition of MLCP as a contractile mechanism. An algorithmic framework for the implementation of the model in finite element programs is derived. Based thereon, simulation results of arteries under time-dependent intravascular pressure, mimicking the scenario during a heart-beat, are analyzed and the influence of the proposed model is shown. Quantitative comparisons with experiments show that the response of the model enables realistic numerical simulations.

Abstract

Knowledge about patient-specific knee joint dynamics is crucial for the decision on therapeutic options in order to restore stability and functional/physiological joint motion after a cruciate ligament rupture. To achieve best possible approximation to the patient's native pre-traumatic knee joint condition, our research focus is concerned with a dynamic three-dimensional knee joint model employing the Finite Element method (FEM) for the assessment of the individual biomechanics. The patient-specific FE-model is automatically generated based on MR image segmentations of relevant anatomical structures of the knee joint: bones, articular cartilages, menisci, and ligaments. Linear and non-linear constitutive models, including initial strains are considered for modelling soft tissues. MR measurements of volunteers with in-situ loading (flexion, internal and external rotation) were used to validate the kinematics of bones and menisci. Analyses of simulation results as well as comparisons to MR measurements at selected flexion and rotation angles are shown in Figure 1. The simulated patient-individual knee joint biomechanics can be used in the decision process in order to restore stability and physiological joint motion after a cruciate ligament tear. Our vision is to establish computer-assisted ligament reconstruction planning in clinical routines.

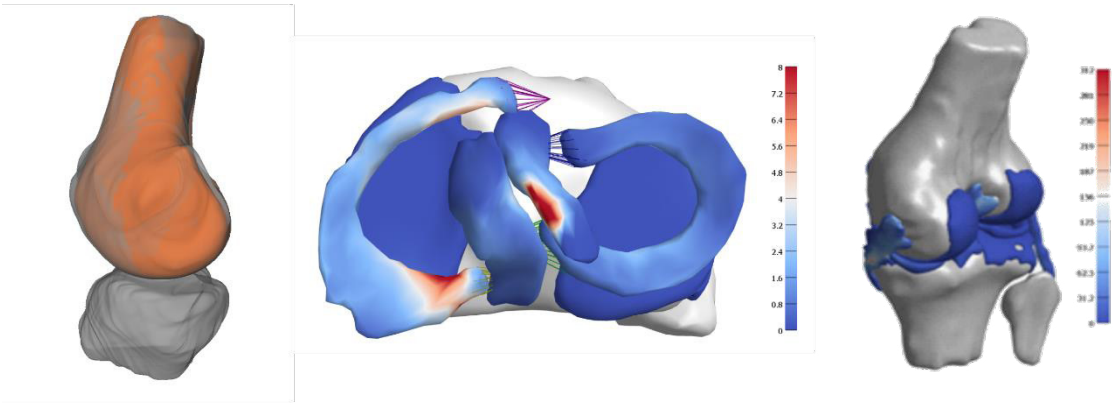

Figure 1: FEM-simulation of a knee joint up to 20° flexion with subsequent external rotation up to 28° and the corresponding stresses [MPa]. Left: comparison of simulation-based femur position (orange) with MR measurement (grey). Middle: meniscus and cruciate ligament dynamics at external rotation. Right: dynamics at external rotation.

Key Words: *blood flow, circulating tumor cell, membrane tension, cell dynamics, hemodynamics*

The membrane tensions of suspended nucleated cells moving in blood flows in microvessels are quite different from those of spreading cells, which is crucial to many pathological processes, such as the metastasis of cancers via circulating tumor cells (CTCs)[1-3]. However, few studies have examined membrane tensions in suspended cells, especially when interacting with other cells of different stiffnesses in low–Reynolds number flows at the cellular level. Taking CTCs as an example, we use the immersed boundary method to analyze the relationship between membrane tensions and their motional behaviors under the influence of fluid–cell–vessel interactions. The effects of vessel diameter and hematocrit on the shear tension and average isotropic tension are also analyzed. The results suggest that the confinement of the vessel wall determines membrane tensions on CTCs until the ratio of the vessel diameter to cell size becomes slightly larger than unity, at which point cell–cell interactions become the crucial factor. The increase in interactions between red blood cells (RBCs) and CTCs with the increase in the hematocrit in larger vessels promotes membrane tensions not only through the migration of CTCs to the vessel wall but also through a reduction in the translational motion and rotation of CTCs. The present study provides support rooted in biofluid mechanics for mechanobiological research on the metastasis and apoptosis of CTCs in microvessels.

A Numerical Study on the Effects of Mechanical Properties of Red Blood Cells on Rheology in Narrow Microchannels

Deyun Liu [1], Kazuyasu Sugiyama [2], and Xiaobo Gong [1*]

[1] Shanghai Jiao Tong University, Shanghai 200240, Peoples R China, x.gong@ sjtu.edu.cn
[2] Osaka University, Osaka 5608531, Japan, Kazuyasu.sugiyama@me.es.osaka-u.ac.jp

Key Words: *Narrow Channel, Large Deformation, Buckling, Fluid-Structure Interaction*

The changes of the mechanical properties of red blood cells including the ratio of surface and volume, and shear modulus affect their dynamical behaviours in microcirculations apparently, and the interaction of cells and their surrounding fluid has a critical impact on the design of microfluidic chips as well. Here, we investigated the large deformations of a single red blood cell in extreme narrow channels and the hydrodynamics associated. The cell membrane was modelled as a hyper-elastic thin shell. The cytoplasm was treated as Newtonian fluid with larger viscosity than the outer fluid. The immersed boundary method was adopted for the fluid-structure interaction. Strict conservation of the surface area and volume of cell were achieved.

Numerical results show that the flow resistance correlates with the capillary number in two different mechanisms. At a relatively high capillary number (> 0.2), the average thickness of the thin film between the cell membrane and the vessel wall dominants flow resistance approximately following lubrication theory. At a relatively small capillary number (< 0.1), cell membranes often present wrinkles, at which the flow resistance is higher than that predicted with lubrication theory. This deviation is due to the inhomogeneous distribution of outer fluid vorticity around the membrane. By increasing the reduced volume of the cell, the wrinkles and the resistance deviation from lubrication theory decrease.

The present study helps in understanding the discrepancy in measure the mechanical property of single cell with narrow channels.

Key Words: *Data Assimilation, Membrane Permeability, Lagrange Multiplier Method, Finite Element Method*

Mass transfer phenomena across biological membranes can be observed everywhere in the human body. Erythrocytes in a blood supply oxygen to cells through the erythrocyte membrane and blood vessel walls. It has been reported that atherosclerosis is caused by the accumulation of low-density lipoproteins under the vascular endothelium. Quantitative methods to measure the permeability of biological membranes are required for further understanding of biological activities in the body and elucidation of circulatory disease mechanisms. As a computational technique using measurement data, the data assimilation method have often been used to improve the accuracy of the data or to estimate unknown parameters. For hemodynamics application, D'Elia et al. proposed a data assimilation method that minimizes the difference between the computational fluid velocity obtained from the steady Navier-Stokes equations and the measured velocity data. In this study, following the concept of D'Elia et al's study, we propose an estimation method for the membrane permeability such that the concentration distribution from the diffusion equation and the measured concentration data are minimized. The diffusion equation with the transport equaiton of the membrane was formlated as the weak form. The equation was descretized using the finite element method, and a minimization problem was set up to minimize the difference in concentration between experiment and calculation using the Lagrangian multiplier method. The system of equations was derived from the stationary condition and the solution was obtained numerically. In order to verify the proposed method, one-dimensional problem was set up. The proposed method was applied to artificial concentration data with noise, and it was confirmed that the proposed method can estimate reasonable values of the membrane permeability coefficients.

Deformation Mechanics of a Red Blood Cell under Shear Flow

Ken-ichi Tsubota[1*]

Key Words: *Biomechanics, Red Blood Cell, Cell Membrane, Viscoelasticity, Boundary Element Method, Mechanical Testing*

Determining the viscoelasticity of a red blood cell (RBC) is important in understanding its mechanics, which can be used to monitor health. Under strong shear flow, elongation deformation of an RBC accompanying a tank-treading (TT) motion increases with fluid shear stress relative to the membrane's viscoelastic stress. Here, the RBC deformation was numerically simulated to understand its mechanical characteristics. The boundary element method was used to couple the viscoelastic deformation of the cell membrane and viscous flow of the surrounding fluids. As a result, deformation and inclination angle of the RBC were related to the fluid traction difference between the suspending and RBC inner fluids [1]. When the viscosity of an RBC is compatible with the suspending fluid, the elongation index responding fluid shear stress is similar to the responding external loads in the optical tweezers stretch, but elongation mechanics differed. By identifying the viscoelasticity of the cell membrane to reproduce published experimental data, the strain hardening elasticity of the cell membrane was identified by modifying the model developed by Skalak et al. [2]; the exponential form of Fung [3] successfully expressed the stronger strain hardening behavior for the latter deformation regime. These results indicate the applicability of the shear flow experiments as a stretch testing method to measure the viscoelasticity of the cell membrane.

Key Words: *Left Atrium, Pulmonary Vein, Hemodynamics, Computational Fluid Dynamics*

Computational approaches to express left atrium (LA) hemodynamics are potentially useful to diagnose LA thrombosis. Recent cohort studies[1] clarified that left upper lobectomy (LUL) with left superior pulmonary vein (LSPV) resection in thoracic surgeries has a higher prevalence of LA thrombosis. Because PV geometries have large patient-specific differences and relative posture of the remaining PVs can be altered by the lobar resection, alteration of the remaining PVs posture after the LUL may affect the LA hemodynamics. This study aims to evaluate the impact of the remaining PVs geometric alteration on LA hemodynamics after the LUL using 4D-CT based computational fluid dynamics simulation.

4D-CT images (20 phases/cardiac cycle) for three lung cancer patients before and after the LUL were acquired in Jichi Medical University hospital. LA surfaces were reconstructed from 4D-CT images and these displacement field were estimated by a non-rigid point registration[2]. Computational simulations of the LA blood flow were conducted by solving the incompressible N.S. equation with the prescribed LA moving-wall boundary condition in a finite difference manner. The wall boundary conditions were treated by the boundary data immersion method[3]. For each patient, we conducted blood flow simulation before and after the LUL. Moreover, we computed an artificial LUL case, in which the LSPV is artificially resected from preoperative geometry to focus on the effects of LSPV resection without changing relative postures of the remaining PVs on the LA hemodynamics.

Obtained results showed that jet flows from each PV into the LA in almost whole cardiac cycles in every case and these jets much progressed in cases with artificial LSPV resection comparing to preoperative case. While after LUL, the collision regions of jet flows changed due to the alteration of the jet flows direction. These findings suggest that the alteration of LA hemodynamics was not only induced by the LSPV resection, but also the alteration of atrial and remaining PV anatomies by the LUL.

The steady motion and equilibrium location of red blood cells (RBCs) in microchannels is a key issue in cellular-scale hemodynamics and microfluidics. However, full information of the dynamic behaviors of cells in 3D circular tubes to varied flow conditions is lacking. We investigated the dynamic behavior of erythrocytes across a wide range of flow rates and beginning locations in order to obtain phase diagrams of the equilibrium state. When shear rates are low ($\dot{\gamma}^* < 0.1$), the equilibrium state of the cell shifts from "Snaking" to "Tumbling", then "Slipper" to "Parachute." For high shear rates ($\dot{\gamma}^* > 0.1$), the equilibrium state of a cell may be either "slipper" or "parachute," depending on its starting position. While both of these factors affect the deformability of erythrocytes, shear modulus has no effect on the pattern of equilibrium state and position, whereas the ratio of internal to external viscosities decreases, and the equilibrium state tends to become "Snaking" or "Parachute" near the tube center. Due to the difference in beginning locations, an erythrocyte's equilibrium state might be "parachutes" or "slippers," with "slipper" erythrocytes traveling quicker and having less membrane tension. Not only does this work provide light on mass transfer mechanisms influenced by RBC dynamic behaviors in microcirculation, but it also paves the way for the development of efficient microfluidic chips for cell sorting.

Key Words: Axial migration, red blood cell, Newtonian fluid, circular channel flow

Human red blood cells (RBCs) are subjected to high viscous shear stress, especially during microcirculation, resulting in stable deformed shapes such as parachute or slipper shape. Those unique deformed RBC shapes, accompanied with axial or nonaxial migration, cannot be fully described according to traditional knowledge about lateral movement of deformable spherical particles [1]. Although several experimental and numerical studies have investigated RBC behavior in microchannels with similar diameters as RBCs [**?**], the detailed mechanical characteristics of RBC lateral movement–in particular, regarding the relationship between stable deformed shapes, equilibrium radial RBC position, and membrane load–has not yet been fully described. Thus, we numerically investigated the behavior of single RBCs with radii of 4 μm in a circular microchannel with diameters of 15 μm or more. The problem was characterized by Reynolds number and the capillary number Ca, which is the ratio between fluid viscous force and membrane elastic force. The power (or energy dissipation) associated with membrane deformations was introduced to quantify the state of membrane loads. RBCs, modelled as biconcave capsules whose membrane follows the Skalak constitutive law [2], is simulated for a wide range of viscosity ratios between the cytoplasm and plasma, for different Re and Ca. Since this problem requires heavy computational resources, we resort to graphics processing unit computing, using the lattice-Boltzmann method for the inner and outer fluid and the finite-element method to follow the deformation of the RBC membrane. Simulations were also performed with different initial RBC centroid positions. Our numerical results demonstrated that, especially for almost inertialless, axial or nonaxial migration of RBC depended on the stable deformed RBC shapes, and the equilibrium radial position of the RBC centroid correlated well with energy expenditure associated with membrane deformations.

Quantitative Prediction of Rolling Dynamics of Leukocyte-inspired Microroller in Blood Flow

Xiaojing Qi[1*], Shuo Wang[1], Shuhao Ma[1], Keqin Han[1], Xin Bian[1], Xuejin Li[1]

[1] Department of Engineering Mechanics, Zhejiang University, Hangzhou 310027, P. R. China, 11924030@zju.edu.cn

Key Words: *Blood cells, Bio-inspired microroller, Rolling dynamics, Drug delivery, Mesoscale modelling*

Magnetic microroller, inspired by leukocyte in the microcirculatory system, represents a promising candidate for targeted drug delivery [1,2]. However, the rolling dynamics of individual microroller in response to controlled changes in shear stress and magnetic field remains largely unknown. Here, we develop a mesoscopic model of the leukocyte-inspired microroller to investigate its locomotion behaviour inside blood vessel under different shear stresses and magnetic torques. We find that the microroller can roll along with the blood flow or move against the bloodstream depending upon the competition between applied magnetic torque and fluid shear stress. Our simulations reveal that the microroller can achieve precise navigation under low shear stress levels. We also probe the effect of blood haematocrit on the dynamic performance of the microroller, which shows that the shear-induced collisions between erythrocytes and the microroller can significantly alter the motion of the microroller, especially under high haematocrit levels. In addition, we examine the rolling dynamics of the leukocyte-inspired microroller in a bifurcating microfluidic channel, demonstrating that the microroller can navigate along the user-defined path. These findings provide unique insights into the rolling dynamics of individual microroller in physiologically relevant blood flow, and offer an objective way for facilitating the design of bio-inspired microrollers in targeted and localized therapeutic delivery with high precision and efficiency.

Study on flow behaviors of hemoglobin-based oxygen carriers through microvessels

Toru Hyakutake[1*], Soto Kambara[2], Yohei Miyoshi[2] and Yuya Tsutsumi[2]

[1] Faculty of Engineering, Yokohama National University, 79-5, Tokiwadai, Hodogaya, Yokohama 240-8501, Japan, hyaku@ynu.ac.jp
[2] Graduate School of Engineering, Yokohama National University, 79-5, Tokiwadai, Hodogaya, Yokohama 240-8501, Japan, hyaku@ynu.ac.jp

Key Words: *Red blood cells, Hemoglobin-based carriers, Lattice Boltzmann method*

Various types of hemoglobin-based oxygen carriers (HBOCs) are currently being developed as transfusion alternatives for solving chronic blood-supply shortage issues arising from rapidly declining birth rates and aging populations. These carriers are also essential for reducing the inherent risks associated with current blood preparation proceses. For example, cellular Hb vesicles (HbVs) that encapsulate the concentrated Hb solution in phospholipid vesicles are being vigorously promoted in Japan and have been recognized as useful alternatives for red blood cells (RBCs). The diameter of typical LEH particles ranges from approximately 200 nm to 250 nm, which is roughly 1/30th the size of a human RBC. Thus, the effect of HbVs will be significant at a microcirculation level, where vessel diameters are smaller than the RBC diameter. Studies focused on RBC and HbV flow distributions at this level will elucidate the effect of HbVs on organ perfusion and tissue oxygen delivery. Therefore, in the present study, the behaviors of flow with mixed RBCs and HbVs in microvessels were analyzed.

In the present study, we adopt the lattice Boltzmann method (LBM) for the computation of flows. The LBM is a relatively new and promising numerical scheme for simulating complex flows and has attracted considerable attention as an alternative approach to conventional Navier-Stokes equations for computational fluid dynamics. One advantage of the LBM is the simplicity of handling complex moving geometries. Therefore, LBM is very effective for the analysis of multiphase fluid flows (for example, those considered in the present study). We treated the RBC membrane as a neo-Hookean model. In this study, we employed the immersed boundary method (IBM) to examine the fluid-membrane interaction between the flow field and deformable RBCs.

In conclusion, the present LBM simulations revealed the flow behaviors of RBC and HbV at a microvascular bifurcation. The partial replacement of RBC by HbV reduces the bias of the oxygen flux. The present result suggests that HbV contributes to reducing the heterogeneity of the oxygen supply, possibly improving the oxygenation of ill-perfused regions. Further numerical analyses based on the arterial-capillary network are needed to clarify the overall effect of HbV transfusion on organ perfusion.

Clinical Relevance: the Key Motivator in Designing and Conducting Computational Studies of the Shoulder

Joseph P. DeAngelis, MD
Carl J. Shapiro Department of Orthopaedic surgery, Beth Israel Deaconess Medical Center and Harvard Medical School

Simulations of the rotator cuff (RC) have the potential to be used to enrich our understanding of the mechanical environment of the tendon and inform clinical decision-making. For these simulations, the ultimate goal is to build a framework that can be used by clinicians to support recommendations for their patients and ultimately improve the patient's quality of life. The clinical translation of such a framework depends on the synthesis of data from a myriad of sources to achieve a useful and accurate clinical recommendation. The ideal framework will be patient-specific, including tendon status and material properties, motion-specific and adaptable to the activities and activity level of the patient, and will use a validated method for estimating the mechanical environment of the RC to estimate tear initiation and progression risk. The framework will also consider the biological and other potential confounding factors that affect the mechanical environment of the RC tendons. To achieve clinical utility, the framework requires feedback from clinicians, ideally comprehensive long-term patient assessments that can be used to quantify the quality of the initial recommendations. The final stages of this framework will provide clear and concise, quantified clinical recommendations easy for the clinician and the patient to understand and to act on. The field has not yet achieved a mature, clinically translatable simulation framework, but the foundation for many of the pillars that this future ideal framework will rely heavily on have recently been built. Through iterative collaboration between scientists and clinicians, we will build clinically effective simulations that will enhance our understanding of RC tear pathomechanics and pathophysiology to ultimately improve patient care.

Therefore, we propose a round table made up of clinicians and scientists evaluate and offer a framework for improved clinical relevance.

Finite Element Model of Articular Sided Rotator Cuff Tear

Mason J. Garcia[1,2*], Patrick M. Williamson[1,2] and Ara Nazarian[1]

[1] Musculoskeletal Translational Innovation Initiative, 99 Brookline Ave, Boston MA, 02215, anazarian@bidcm.harvard.edu
[2] Boston University Department of Mechanical Engineering, 110 Cummington Mall, Boston MA, 02215, bumeche@bu.edu

Key Words: *Finite Element Modelling (FEM), Rotator Cuff Tear (RCT)*

Introduction:

Rotator cuff tears (RCT's) occur in about 22% of the population over 50 years old, with the prevalence increasing as age increases [1]. Among those with RCT's about 65% of tears are asymptomatic [1]. Of patients that have asymptomatic RTC's, 36% will develop symptomatic RTC's within three years [2]. With the population expected to double for the 65–85-year-old population by 2050[3], it is increasingly important to tear progression. The aim of this study is to use Finite Element Modelling (FEM) to better understand the strains the supraspinatus experiences for an articular sided partial tear.

Methods:

To model partial tear on the supraspinatus, a validated FEM of an intact tendon first most be contructed. The articular and bursal side of the supra spinatus will be split to account for the varying material properties on each side. Each side will then be futher split into subsections to define the heterogenous material properties of the supraspinatus. The supraspinatus will be constrained for no translation or roation at the tendon insertion site of the greater tubercle of the humeral head and pulled to 4.14mm to match the conditons applied to a cadaveric study that was conducted to measure surface strain of the articular and bursal side of the supraspinatus. The strains will be compared to validate the FE model. To simulate partial tear, a new boundary condition will be applied where only the bursal side of the tendon insertion site is contrained.

Results:

The model was validated within a maximum of a 3% strain difference between articular and bursal X and Y principle strains when compared to the cadaveric data. The strain from the FEM of partial tear showed the same strain when the tendon ensertion was completely connected.

Discussion:

The goal of this study was to create a validated FEM to be used to model partial rotator cuff tears to better understand the strains associated with tears to help elucidate tear initation and propagation. Our initial findings indicate no differences in strain when the articular sided insertion of the tendon is not constrained. The next steps are to make a more refined model that includes the infraspinatus and give regions close to the inrestion zero stiffness to replicate tears and assess strain differences. These findings may help to better understand the onset of tears by evaluating the strain differences between a partially torn and a healthy tendon.

Influence of Implant Design, Placement, and Soft Tissue Restraint Upon Shoulder Mechanics after Reverse Shoulder Arthroplasty

Joshua Johnson[1*], Brendan Patterson[2], and Donald D. Anderson[3]

[1] University of Iowa, 2181 Westlawn, Iowa City, IA 52242, joshua-e-johnson@uiowa.edu

Key Words: *Reverse Shoulder Arthroplasty, Post-impingement Instability, Dynamic FEA*

Combinations of implant design elements, positioning, and soft tissue tensioning are used to improve pre-impingement range of motion (ROM) and stability after reverse shoulder arthroplasty (RSA). However, RSA patients may occasionally undergo motions beyond impingement.

We implemented a dynamic, explicit FE model of RSA validated against experimental contact pressure during scapular impingement [1]. Bony (scapula, humerus) and soft tissue (subscapularis, deltoid) geometries were acquired from Visible Human CT scans. Bone and glenoid components were modeled as rigid, while soft tissues, polyethylene liner, and the bony scapular impingement region were modeled as deformable. Contact was defined at all relevant interfaces. Soft tissues were tensioned and wrapped around the joint/implant prior to motion. With the scapula fixed, humeral rotations were prescribed about anatomic axes. The mechanical trade-offs associated with various implant design features, placement, and subscapularis restraint/quality were investigated.

Increasing glenosphere lateralization increased impingement-free ROM, but the deltoid force required to elevate the arm [2] and the torque required for external rotation [3] also increased. Presence of the subscapularis was found to restrain post-impingement instability [4]. However, external rotation torque increased with increases in subscapularis stiffness [3]. In general, absence of the rotator cuff musculature produced greater impingement likelihood and post-impingement instability. Placing the glenosphere in neutral version together with rotating the liner posteriorly resulted in the greatest post-impingement stability [5]. While providing greater stability during abduction, a valgus angle of inclination liner design resulted in greater post-impingement instability during external rotation and extension, made worse by the absence of the subscapularis [4].

Simulating the full range of functional activities, while incorporating soft tissue tensioning and restraining effects, may aid in preoperative planning to improve pre- and post-impingement stability and overall outcomes after RSA.

Key Words: *Paediatric, Musculoskeletal Modeling, Digitized Fascicles, Finite Element*

This research aims to develop a computational workflow to create paediatric musculoskeletal finite element models to understand infant muscle biology and mechanics. Muscle fibre fascicles (FFs) and connective tissues were digitized in a 6-month-old female cadaver; TS muscles were outlined from origin to insert attachment sites and digitized using a MicroScribeTM G2X Digitizer (0.05 mm accuracy; Immersion Corporation, San Jose, CA). The digitized data were used to create qualitative 3D muscle models in Autodesk® Maya® [1]. Fascicles of each muscle were wrapped by 2D convex skin grids and then converted into volumetric tetrahedral meshes. Information from fibre fascicles was used to define the fibre orientation as inputs for a Transversely Isotropic Mooney Rivlin material property in a finite element model. The FE model was set in FEBio (Salt Lake City, UT, USA); model parameters were tuned to reproduce the passive range of motion of in vivo and cadaveric experiments [2]. Lagrange strain was computed from the incremental applied load (200N) at the calcaneus bone to mimic antagonist ankle dorsiflexion loading. Maximum strains were observed at the myotendinous junctions of the muscles, and non-uniformity of stress and strain patterns were observed, suggesting that there are local inhomogeneities of mechanical strains and biological remodelling of these tissues. To reach the maximum passive dorsiflexion, nearly 80%, 50%, and 10% strain were observed in lateral gastrocnemius, medial gastrocnemius, and soleus. We developed robust computational modelling (converging time <1min with single CPU) to map the stresses and along-fibre strains in triceps surae muscles, suggesting rapid muscle remodelling in origin and insertion regions of the muscle. Future work will continue digitizing more specimens to create a statistical shape modelling of paediatric TS muscles and develop a real time surrogate TS muscle musculoskeletal model applicable in clinics. This work is a step forward in development of biomechanical models from high fidelity anatomical data.

Key Words: *cardiomyopathy, heart left ventricle, machine learning, 3D reconstruction*

Automatic diagnosis of dilated cardiomyopathy based on ultrasound images is a challenging task, because pixel intensity levels in the images are not related to the physical properties of the tissue, as well as there is poor signal-to-noise ratio in images and weak echoes. Therefore, this study develops an automated methodology for 3D reconstruction and analysis of heart ventricle (LV) in patients with cardiomyopathy that can be divided into three main steps: (1) machine learning algorithms to extract LV and relevant parameters, (2) geometrical algorithms to reconstruct 3-dimensional model and (3) finite element method to analyse the mechanical response of the left ventricle under different loading conditions. Collected dataset consisted of 1809 images with apical view and 53 images with an M-mode view from cardiomyopathy patients at clinical facilities in the United Kingdom and Serbia. Methodology for analysis of apical view was based on segmentation of LV using U-net convolutional neural network [1] after which the segmented region was bounded with rectangle, where the longer side corresponds to left ventricular length (LVL). Regarding the M-mode view, traditional algorithms such as adaptive histogram equalization, template matching, Canny edge detection, and thresholding are used to extract internal dimension (LVID), posterior wall thickness (LVPW), and interventricular septum thickness (IVS), due to the smaller number of images. When manually annotated and automatically extracted parameters are compared, a dice coefficient of 92.091% for segmentation is obtained, as well as an average root mean square error (RMSE) of 0.3052cm for parameter extraction in apical view images and an average RMSE of 1.3548cm for parameter extraction in M-mode view images. Based on extracted left ventricle length, radiuses, wall thicknesses, and user-supplied divisions, 3D parametric model of LV is reconstructed, which can be used to replicate the entire cardiac cycle using Finite element method (FEM). Described methodology is integrated into SILICOFCM platform [2]. Fully automated cardiomyopathy identification, 3D reconstruction, and cardiac cycle modeling of the left ventricle utilizing ultrasound pictures can assist doctors in making more timely judgments and establishing more accurate therapies. The approach is now available on a user-friendly platform in order to help clinicians make faster decisions and establish reliable treatments.

Key Words: *echocardiography, left ventricle, membrane finite element, cardiac cycle.*

One of the very effective tools for tracking the cardiac cycle is echocardiography. This technique helps doctors to assess the heart function of a patient. Echocardiography is the most commonly applied technique for non-invasive assessment of cardiac state. In this paper, we presented the semi-automatic generation of the solid left ventricle model based on the images acquired from echocardiography. We generated model from the echocardiographic image at the start of diastole. Starting from there, we prescribed displacements using models generated at other time instances of the echocardiographic data. Since the dominant stresses lie in the sheet planes, while normal stresses in the wall normal directions are of the order smaller, we explored a possibility to model heart wall by membrane finite elements, hence considering the wall as a thick membrane (shell without bending effects). The membrane element is composite, containing layers over the thickness and variation of the direction of fibers. The membrane elements enables us to simulate heart mechanics which are much smaller and simpler for use than conventional 3D models. As a material model, we used the recently developed computational model [1] based on Holzapfel experiments [2,3] for the determination of passive stresses within cardiac tissue. The presented approach of modeling mechanics of the LV can serve as the basis for practical applications since it is based on the true patient-specific geometry and relies on experimental constitutive relationships.

Recent experiments on hydrogels subjected to large elongations have shown elastic instabilities resulting in the formation of geometrically intricate *fingering* patterns. In this talk, we present a robust computational framework to simulate this complex material response from the onset of instability to the post-bifurcation behavior. We discuss the numerical challenges stemming from the non-convexity of the strain energy density in the near-incompressible, large-deformation regime, which is responsible for the coexistence of multiple equilibrium paths with vastly-different, sinuous deformation patterns immediately after bifurcation. We show that these numerical challenges can be overcome by using high order of interpolation in the finite element approximation, an arc-length nonlinear solution procedure following the equilibrium path of the system, and a parallel implementation enabling large-scale simulations. The resulting computational approach provides the ability to conduct highly-resolved, truly quasi-static simulations of complex elastic instabilities. Finally, we present numerical results demonstrating the ability of the path-following approach to describe the full evolution of fringe and fingering instabilities observed experimentally. Importantly, we observe that the robustness of the static solution procedure enables complete access to the multiplicity of solutions occurring immediately after the onset of bifurcation, as well as to the settled post-bifurcation states.

Key Words: Rubber elasticity, Micromechanics, Constitutive modelling, Hydrogels, Elastomers

Understanding the relationships between network architecture and mechanical properties in crosslinked networks is critical for the design of soft materials such as elastomers and hydrogels. Yet, commonly-used constitutive theories of rubber elasticity (e.g. the 8-chain or the full-network models) rely on idealised network representations which ignore the role of network imperfections. Alternative representations have been proposed based on Bethe lattices in the context of linear elasticity (e.g. the Phantom model) but it is unclear how such approaches can be extended to large deformation. A new strategy is needed to explore structure-property relationships based on more realistic network repesentations, which could in turn inform the development of predictive constitutive theories.

In this contribution, we use computational random network simulations to investigate the elastic properties of hydrogels, building on our previous works [1, 2]. A new algorithm is proposed to generate random networks with controlled topology in terms of crosslink functionality, chain density, and chain end-to-end distance distribution. Several topological features are considered, including the degree of interpenetration of the chains, the presence of topological defects (dangling ends, loops), and polydispersity. The mechanical behaviour of random networks is simulated up to large deformations, and results are compared to available semi-analytical estimates and experimental data for tetra-PEG hydrogels [3]. Implications for the design of networks with improved properties are discussed.

Key Words: Polymer, Simulation, Tensile strength, Radius of gyration, Entanglement

Polycarbonate finds a wide range of applications as structural materials and thus is drawing increasing attention in both scientific and industrial communities, owing to the prominent mechanical and physical properties. It is widely accepted that polymer mechanical properties are essentially related with the molecular structure [1]. In our previous coarse-grained molecular dynamics (CGMD) simulation for polycarbonate, the effect of molecular entanglement on maximum stress was investigated. As the number of entanglements was varied by altering the molecular weight [2], the causal effect of the number of entanglements on maximum stress remained unclear by confounding with the effect of molecular weight. This study therefore aims to reveal the effect of chain molecular entanglement and spatial distribution on fracture behavior as follows: The molecular entanglement, spatial distribution, and fracture behavior are quantitatively described by the average number of entanglements per monomer (N_e), root-mean-square of radius of gyration (R_g) and maximum stress ($\sigma_{\max}$), respectively. In this simulation, uniform weight polycarbonate structures with the systematical variation of N_e and R_g are generated by varying equilibrium temperature profiles and initial arrangements of molecules, respectively. Uniaxial tensile deformation is applied to each simulation cell at a constant strain rate, and the stress-strain relationships are obtained. We found significant effects of N_e and R_g on the maximum stress; for instance, the molecular structure of a higher radius of gyration leads to higher maximum stress with a constant molecular weight. Bivariate nonlinear regression analysis is performed to obtain description of maximum stress as a function of the radius of gyration normalized by molecular weight and the number of entanglements.

Key Words: *hydrogel, water content, physical adhesion, adhesion energy*

Hydrogels are widely used in flexible electronics and biomedical fields due to their superior stretchability and biocompatibility. Previous studies have demonstrated that the water content has significant effect on the elastic and fracture behaviours of hydrogels. However, the effect of water content on hydrogel adhesion has not been systematically explored. In our study, we first carry out a series of experiments on polyacrylamide hydrogels with a wide range of water content and find that the physical adhesion properties of polyacrylamide hydrogels are related to the water content. With the decreasing water content, the adhesion energy of polyacrylamide hydrogels undergoes four stages. The surface chain density, water molecules on the surface, bulk energy dissipation, and effective contact area of the polyacrylamide hydrogel are considered to synergistically contribute to these four stages. Specifically, at extremely low water content of about 30%, polyacrylamide hydrogels exhibit one order of magnitude higher adhesion energy than that at relatively high water content. It is also found that with the decrease of water content, the maximum peeling force presents a similar trend to that of the adhesion energy. To fully understand the effect of water content on hydrogel adhesion, a finite element method is further adopted to simulate the water-affected adhesion of the hydrogel attached to a rigid substrate, in which some parameters can be obtained from the experimental work. According to these discoveries, we can control the adhesion performance of a hydrogel by simply adjusting the water content, and even achieve reversible adhesion.

Key Words: *Double Network Hydrogels, Machine-learning, Coarse-grained Model, Molecular Dynamics*

Double network (DN) hydrogels are composed of two layers of crosslinked polymer networks. They have higher stretchability and greater toughness than regular hydrogels, making them promising applications in tissue engineering, drug delivery carriers, fluid actuators, and other fields. However, the experimental study of mechanical properties of DN hydrogels has some shortcomings, such as complex experimental process, high research cost, and low efficiency. Herein, coarse-grained molecular dynamics (CGMD) models of DN hydrogels are proposed by combining molecular dynamics (MD) simulation and machine learning (ML), to learn the relationship between crosslinked networks structure and their mechanical properties. The DN hydrogel CGMD model developed by ML simplifies the details of the all-atom model, reduces the degree of freedom of the simulation system, and saves the computational cost. The results obtained from the CGMD simulations are used as training data sets. The force field parameters are optimized by the artificial neural network. The results of this work provide general CGMD FF parameters and illustrate that it is possible to simulate large-scale complex hydrogels model models.

Mechanical Property Prediction of Single-Network Hydrogel Using Machine Learning Framework

Jing-Ang Zhu[1*] and Zishun Liu[2]

Key Words: *Machine learning, Hydrogel, Mechanical property, Predictive modeling*

Hydrogel has a complex network structure with inhomogeneous and random distribution of polymer chains. Much effort has been paid to fully understand the relationship between mesoscopic network structure and macroscopic mechanical properties of hydrogels. Recently, machine learning algorithms are becoming an important tool in the fields of mechanics of materials, attributed to its power to predict materials properties. In this study, we develop a machine learning framework to predict the mechanical properties of single-network hydrogel from polymer network structures. The constructed deep learning models are able to capture the nonlinear mapping from mesoscopic hydrogel network structural model to its macroscale mechanical property. The implemented machine learning framework provides a guidance to predict the nominal stress–stretch curves of hydrogels under uniaxial tension, and the framework also demonstrates the potential for predicting mechanical properties under more complex boundary conditions. Our results show that the end-to-end machine learning framework can effectively predict the mechanical properties of hydrogel within a wide variety of mesoscopic network structures, which demonstrates that the deep learning models are able to capture the internal relationship between complex network structures and mechanical properties. We hope this approach can provide guidance to structural design and material property design of different soft materials.

Key Words: *Additive manufacturing; Discrete element method; Polymer; Glass fiber; Packing density; Surface roughness*

Fiber-reinforced polymer composites printed via additive manufacturing (AM) have gained great popularity because of their enormous potential for various applications in the automotive, aerospace, and biomedical industries. The main concerns on the AM of high-quality composite parts are the void content and fiber orientation, which are closely associated with the packing characteristics of powder beds. A discrete element model has been developed to study the packing quality of glass fiber/polyamide 12 composite powder in powder bed fusion AM. The geometric shapes of polymer powder particles and fibers are represented by multi-sphere particles and sphero-cylinders, respectively. The numerical model helps to understand the flow dynamics of composite powder particles and the formation mechanisms of voids in the powder packing process. The numerical model has been utilized to analyze the effects of packing parameters on the packing quality of the powder bed. The simulation results reveal that the increase of the powder layer thickness is beneficial to increasing the packing density and lowering the surface roughness of the powder bed. A high spreading velocity degrades the packing quality of the powder bed. A small number of fibers in the composite powder are in favor of the packing quality, while excessive fibers reduce the packing quality of the powder bed. The numerical simulation can serve to guide processing parameter optimization for improving the dimensional accuracy and minimizing the porosity in AM-printed parts.

Structural optimization design of intelligent hydrogel-based soft devices

Key Words: *hydrogel-based soft device, topological optimization, moving morphable void and component, geometric nonlinearity, anisotropy*

A systematic approach is proposed to address the issue of shape and topology optimization of hydrogel structures involving recoverable large deformation in this paper. The thickness of the hydrogel layer and the fiber orientation of the fiber-reinforced hydrogel are taken as design variables in the shape optimization. The outline and material distribution of the hydrogel structures are described as the design variables by the explicit moving morphable voids and components in the topology optimization. In order to deal with the convergence issue of the intermediate process of nonlinear optimization, a material interpolation model is established and an adaptive mesh technique is used. Furthermore, the objective function is the displacement of specific nodes to ensure that the swollen structure achieves a unique actuation effect. The adjoint sensitivity is derived based on the mapped element density and the boundary evolution of the structure. Finally, several examples of optimization of isotropic and anisotropic hydrogel structures are used to prove the effectiveness and applicability of the proposed method. 4D printing experiments are also provided to demonstrate that the explicit topology obtained by this method can be directly used in the manufacture of hydrogel based soft devices.

Key Words: *Shape Memory Hydrogel, Constitutive Model, User-Subroutine*

Shape memory hydrogel (SMH) is a new type of the soft smart material, which can transfer from the temporary shape to initial shape when immersed in water. Different with the traditional shape memory polymer, the shape memory process of SMH is an adiabatic process, and the excellent deformability of the hydrogel allows us to pre-program more complex temporary shape. There is no constitutive model that can describe the shape memory behavior for hydrogels induced by chemical potential in an adiabatic process before. In this work, a constitutive model for SMH induced by chemical potential is established. In proposed model, we consider that the SMH consists of two phases, dense phase and sparse phase. The stored deformation is introduced in the dense phase to describe the shape memory effects (SME) of the SMH. The proposed model is further implemented in ABAQUS using the user-subroutine UMAT. We simulate SME of SMH under uniaxial loading, three-point bending, twisting. The comparison between the simulation and the proposed model for the SME of SMH under uniaxial loading shows good consistency. From the simulation for three-point bending and twisting loading cases, it can be demonstrated that the proposed model can describe the SME of SMH under complex and large deformation.

Key Words: Metamaterials, Reusable Energy Manipulation, Isotropic Microarchitectures

This work approaches the problem of the design of mechanical metamaterials including, as a distinguishing feature, instabilities in the elastic regime. Among the various opportunities offered by this characteristic [1], is the manipulation of the deformation energy. In this sense, metamaterials including elastic instabilities are known to exhibit reusable energy-trapping or energy-dissipation [2].

We present a novel methodology for the analysis of microarchitectures including instabilities. The strategy largely reduces the computational effort if compared with full models of non-linear volumetric finite elements or with non-linear beam elements. As a consequence, it allows to enlarge the analysis to more unit cells within the body of the metamaterial and to evaluate efficiently a greater number of topologies, proving to be especially suitable for use in processes of optimization of the microarchitecture.

Noting that existing designs of this class of materials only achieve energy manipulation in specific predifined loading direction, in this work, we center the design aim in obtaining reusable multidirectional isotropic energy manipulation with this technique. This is in accordance with a more realistic use of the metamaterials where general boundary condition do not establish a priori the loading direction.

Key Words: *Computational Material Design, Metamaterials, Low-frequency noise attenuation.*

For years, the concept of metamaterials has been used in the field of acoustics to refer to architected materials with the unnatural ability of attenuating sound in certain frequency bandgaps, thanks to local resonance phenomena. In this context, novel numerical tools under the Computational Material Design (CMD) umbrella, including multiscale frameworks, model-order reduction techniques, and topology optimization methods, have been combined to characterize such kinds of exotic behaviours enabling the design of optimal acoustic metamaterials with enhanced sound attenuating properties. In particular, a computational homogenization model is proposed, which is capable of capturing the effective macroscopic response triggered by local resonances in the metamaterial's microscale [1]. This numerical model has been successfully validated through an experimental sound transmission loss (STL) measurement of a 3D-printed acoustic metamaterial prototype [2].

As a next step in the computational design of acoustic metamaterials, the novel concept of Multiresonant Layered Acoustic Metamaterial (MLAM) is proposed as a potential solution to two major challenges still present in the acoustic metamaterials technology: (a) the narrowband nature of their attenuating capabilities, and (b) the complex manufacturing processes. The MLAM technology addresses the first issue by basing its design on coupled-resonances mechanisms that translate into a double-peak STL response (allowing to extend the attenuation bandwidth, even at low-frequency ranges). Furthermore, the layered-based structure makes the MLAM suitable for large scale manufacturing, for instance, through well-established lamination and die-cutting processes presently available in the industry [3]. In this regards, applying CMD tools to the MLAM design can potentially make the acoustic metamaterials technology feasible for the market.

Key Words: Modular-topology optimization, Free material optimization, Wang tiling

Designing efficient modular structures and mechanisms demands solving two optimization task: optimizing the topology of individual modules and choosing their optimal placement in a product such that the modules synergistically cooperate. In our previous work on the minimum-compliance design of modular truss structures [1], we addressed this problem in a concurrent setup, combining a meta-heuristic method for updating the modular assembly plan with a second-order cone programming to generate the optimal truss-like topologies of the modules. Here, we present our recent results [2] on a computationally more efficient, bi-level sequential strategy applicable to continuum structures and mechanisms.

First, using the free material optimization, we determine the optimized distribution of stiffness tensors at the product scale. Next, we partition the stiffness tensors into a given number of clusters by a novel deterministic algorithm. Interpreting the outputs of the clustering algorithm within the Wang tiling formalism [3] yields the sought-for assembly plan. Finally, topology of individual modules is obtained from the standard, single-scale topology optimization based on the Solid Isotropic Material with Penalization interpolation scheme with the design space reduced by a mapping reflecting the modular assembly plan.

We illustrate the performance of our method on four two-dimensional problems: the modular minimum-compliance Messerschmitt-Bölkow-Blohm beam, two modular compliant mechanisms (an inverter and a gripper), and a combined modular design of both mechanisms, illustrating the reusability of the optimized modules. We demonstrate that by choosing the number of clusters we can compromise between a Periodic Unit Cell-based design of a material microstructure and a traditional full-scale topology optimization. Our method thus opens the way for the rational design of modular metamaterials and mechanisms at the material level.

Key Words: *Topology Optimization, Multi-Material, Stress, Microstructures, Homogenization*

Structural optimization plays an important role in the construction industry, leading to more material-efficient structures, promoting then the sustainability of this sector. One of the strategies to perform structural optimization is through Topology Optimization (TO). Single-Material Topology Optimization (SMTO) has been extensively studied over the past decades (see e.g., [1]). Regarding the Multi-Material Topology Optimization (MMTO), there is not that much work especially in microstructural design. MMTO is a current research topic, boosted by rapid developments in Multi-Material Additive Manufacturing (MMAM) (see e.g., [2]). It has been shown that multi-material design solutions, compared to single material, can lead to better performance (e.g., compliance and stress levels) [3-5].

This work addresses MMTO of a periodic composite material unit-cell considering two solid materials plus void, with properties predicted by homogenization, using strength and stiffness design criteria. Firstly, the compliance minimization with mass constraint MMTO problem is solved here. Then, one performs a stress-based MMTO problem where the maximal von Mises stress is locally minimized in the unit-cell. Two different types of design solutions are investigated in this latter case. On one hand, the two solids coexist being bonded together across sharp interfaces. On the other hand, a Functionally Graded Material (FGM) is obtained as an extensive smooth variation of material properties on account of varying composition's volume fractions of both solids throughout the design domain. From a computational cost viewpoint, performing the stress-based MMTO has two main bottlenecks: the stress sensitivity analysis and the optimizer runtime. Therefore, the stress derivatives are computed using the adjoint method in a parallel fashion, and the optimizer (MMA, see [6]) is here parallelized to speed-up its runtime when many constraints (say thousands of stress constraints) are considered.

The results show that multi-material designs can outperform single-material ones, both in stiffness and strength design criteria. More specifically, the obtained optimal designs of the compliance-based MMTO are stiffer and stronger than the single-material counterparts for the same mass requirement, on account of removing all void present in the microstructure. On the other hand, the stress-based MMTO designs for the same material volume show a decrease in the maximum stress on the microstructure on account of allowing an increased compliance. The FGM designs approximate fully stressed designs which excel in stress mitigation.

Topology optimization is an effective design tool for generating novel, high-performance material architectures. In particular, multi-material microstructural designs have demonstrated superior properties [1,2]. In this work, we extend the neural-network-based representation, sensitivity analysis, and topology optimization proposed in [3] to design microstructures. The salient features of the proposed framework are: (1) the number of design variables is only weakly dependent on the number of materials considered, (2) it inherently guarantees that the partition of unity is satisfied, (3) it leads to a crisp and differentiable material interface, and (4) supports automatic sensitivity analysis for different objectives. We demonstrate the framework using numerical experiments and validate via physical testing of printed components.

New trends in additive manufacturing have been influencing the design phase of structures in order to unlock unexplored possibilities in terms of achieved geometries and performance. In this regard, several mathematical techniques have been proposed in the scientific and industrial community for the design of both macro- and micro-layouts, properly engineered for diverse objectives.

We present a two-step multiscale topology optimization framework for the design of innovative cellular materials at the microscale, and for the identification of optimized multi-material configurations at the macroscale. Firstly, we employ the microSIMPATY algorithm to devise a set of periodic reference cells that target desired physical goals and comply with given design constraints [1]. This ensemble is referred to as a dictionary of cells. As a second phase, we employ the newly-designed cells to topologically optimize the macroscopic structure, by identifying different regions of the domain where the cellular materials have to be alternated, in accordance with prescribed objectives and requirements [2].

After the formalization of the multiscale paradigm, the proposed algorithm is verified and validated for the design of patient-specific orthopedic insoles, by proposing innovative solutions that outperform standard approaches [3].

Abstract

A theoretical investigation is developed to study the wave dispersion characteristics of imperfect functionally graded material (FGM) sandwich cylindrical shells composed of metal core and two functionally graded materials (FGMs) surface layers in the thermal environment. The temperature-dependent material properties are assumed to vary continuously along the thickness direction. Two types of porosity in FGMs layers of sandwich shells are considered. To describe the porosity effects, the porosity function composed of the porosity distribution function and porosity volume fraction is introduced. A novel thermal strain energy calculation method for cylindrical shell structures in high-temperature environments is developed. The Hamilton's principle is used to derive the wave motion equations, which govern the wave propagation behaviors. The analytical dispersion relations for the wave propagation of imperfect FGM sandwich shells in a thermal environment are obtained by solving a generalized eigenvalue problem. In addition, detailed studies are conducted to emphasize the parameter influences on wave propagation characteristics of imperfect FGM sandwich cylindrical shells.

Keywords: functionally graded sandwich structure; porosity; cylindrical shell; wave propagation; thermal stresses.

Computational Metamaterial Beam Modeling of Topological Phase Transition via Periodic Alternate Elastic Foundation

Guifeng Wang[1], Zhenyu Chen[2] and C.W. Lim[1,*]

[1]City University of Hong Kong, Tat Chee Avenue, Kowloon, Hong Kong SAR, P.R. China

[2]The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong SAR, P.R. China

Abstract

This study investigates the bending characteristics and topologically protected wave propagation of phononic crystal beam on periodic alternate linear elastic support. Timoshenko beam theory is employed to construct a computational model and derive the vibration governing equation. Subsequently by applying Bloch theory, the theoretical dispersion relation is calculated by transfer matrix method (TMM). The accuracy and reliability of TMM solutions are then verified by comparing with the finite element numerical results. Minor difference due to the assumption of Timoshenko beam theory is observed. A new method by tuning stiffness of elastic foundation is proposed in this study to break spatial symmetry and to tune the band structure. It is well acknowledged that a homogenous beam resting on elastic foundation exhibits a band crossing (BC) point and a bandgap which starts from 0 Hz. After breaking system symmetry by tuning elastic support in a periodic alternate manner, the BC point is broken and the other bandgap occurs. Furthermore, mode shape inversion can be observed and Zak phase transition can be calculated, which are essential for topological design purposes. Based on a unit cell analysis, we propose a supercell model by periodically arranging unit cells with the corresponding phase states and the topologically protected interface mode (TPIM) is analyzed. A parametric study of elastic foundation tuning parameter on TPIM frequency and quality factor is conducted. Finally, we design several sections or material defect conditions to demonstrate the defect- and disorder-immune properties of this beam-foundation system. The newly proposed topological phase transition generation mechanism can provide ideas and be extended to other mechanical and dynamic systems.

Keywords: elastic foundation; metamaterial; Timoshenko beam; transfer matrix; topological protected interface modes.

Key Words: Thermal devices, Heat manipulators, Thermal metamaterials, Optimization, Isogeometric analysis (IGA)

Recent advances in material science and physics have sparked a renaissance in heat transfer research. Accordingly, the remedies to global issues such as global warming and the energy crisis also ask for advanced heat transfer devices, that can provide improved efficiency, accuracy, adaptiveness, tunability, and compactness compared to traditional heating, cooling, and harvesting energy. At the macroscale, heat manipulators are one such device that controls and manipulates the heat flow to achieve a specific objective (such as concentrating heat flux at a specific region, cloaking the obstruction in heat flow, etc.). The heat manipulators largely avail of the conductive thermal metamaterials due to their well-defined structure and unique properties [1, 2] that are not possible with naturally occurring materials. In a thermal metamaterial-based heat manipulator, the control on heat conduction is achieved by engineering the thermal conductivity, and consequently, the thermal design plays a pivotal role in its performance and reliability. The present work focuses on maximizing the efficiency of several heat manipulators with keeping manufacturing feasibility in consideration. In our work, we consider a thermal metamaterial composed of two materials as a heat manipulator. The effect of properties of member materials, their configuration, as well as incident flux on the objectives of the heat manipulators, is studied [1, 2, 3]. We also demonstrated a heat manipulator with dual objectives and its sensitivity to shapes, material properties of member materials, and dependency on each objective. Isogeometric analysis (IGA) (for solving the boundary value problem) and a gradient-free optimization algorithm are utilised.

Key Words: *Diamane, Functional group, Vibration properties, Molecular dynamics simulation*

Low dimensional sp^3 carbon nanostructures have attracted increasing attention recently, due to their unique properties and appealing applications.[1-3] The single layer diamond - diamane, a two-dimensional (2D) form of diamond with a bilayer sp^3 carbon nanostructure, has been initially predicted in 2009,[4] while its experimental synthesis has only been reported in 2019.[5]

This work carries out a comprehensive study on the impacts from functional groups on the vibration properties of diamane targeting the ultra-sensitive sensing applications. Based on large scale molecular dynamics simulations, different functional types are investigated, such as the ethyl, methyl and phenyl groups. The results show that different functional types lead to different local bond reconfigurations, and introduce different impacts on the vibration properties of functionalized diamane. Furthermore, the content and distribution of functional groups are also studied to illustrate their influence on functionalized diamane's vibration properties.

Previous study has revealed that the diamane has excellent vibration properties, which are promising for the construction of ultrasensitive resonator-based sensors.[3] This work provides a comprehensive understanding of the influence from functional groups on the vibration properties of functionalized diamane, which should be beneficial to the tuning of ultrasensitive nano resonators.

Phase change materials for thermoelectric micro-energy harvesting

Santiago Madruga[1*]

Low-consumption electronics, such as wireless sensors, wearable electronics, or embedded devices, are employed to monitor industrial processes, environmental variables, health parameters, etc. Low-power sensors are placed in locations ranging from the human body to distant spacecraft. While batteries usually power them, applications involving remote locations, extreme conditions, or the of autonomous systems make batteries impractical. Among the different autonomous sources of power aimed at low-power sensors, thermoelectric energy emerges as one of the most reliable renewable energy sources.

Thermoelectric generators transform temperature gradients across them into electrical energy through the Seebeck effect. Efficient TEGs demand a significant temperature difference between the semiconductor junctions. This drawback limits their use to circumstances where a high thermal gradient is available. An emerging solution to mitigate the limitation of low efficiency is to employ a heat storage unit to generate sustained temperature gradients. In this way, temperature fluctuations in time are transformed into temperature gradients in space. Heat storage units based on latent heat, as the Phase Change Materials (PCM), are especially convenient because of their exceptional thermal energy density, and that part of the energy flowing into the PCMs is used to change their phase instead of homogenizing thermal gradients.

We show how increasing the heat transfer in the heat storage unit embedding the PCM in metallic foams multiplies the electric energy output an order of magnitude with respect to conventional designs of thermoelectric micro-energy harvesters [1]. These designs can power sensors for structural health monitoring in aircraft, monitoring in spacecraft, or harvest daily thermal fluctuations [2, 3]. Also, we present a new concept to strongly enhance the conversion of ambient thermal fluctuations into electric power using the dependence with the temperature of the surface tension of liquids (Marangoni effect) [4]. Since it is based on a fundamental principle, it can be used as a foundation for further improvements to optimize the output of thermoelectric devices to power low-consumption electronics.

Key Words: Multiscale optimisation, shell structures.

This abstract presents the development of multiscale optimisation methods for 2D shell like structures manufactured using 3D printing technologies, it builds on the groups activities in 3D multiscale optimisation [1]. A novel parameterisation of a slowly changing small-scale geometry is used to produce a range of responses, most notably coupling of in-plane and out of plane characteristics to allow complex behaviour to be arrived at via formal optimisation approaches enabled by adjoint sensitivities. The shell formulation used allows large structural response to be considered and the non-linear responses to be optimised via a grading of the small-scale geometry characteristics.

Four design variables are used to describe the small-scale geometry. This small-scale geometry populates the large-scale shell domain and is the same thickness of a the shell but varies gradually in the the in-plane direction. The characteristics of the small-scale geometry is determined through homogenisation theory [2] for the in-plane stress-strain (analogous to the A term in Classic Lamination Theory (CLT), bending-moment (D) and coupling between bending and in-plane behaviour (B). A fourth order polynomial is then fitted to each of the 18 unique terms of the A, B, D matrices as a function of the four design variables describing the small-scale. These equations are the constitutive equation which link the design variables to the local shell characteristics. The small-scale geometry parameterisation is such that the top and bottom surfaces of the geometry can have a varying in-plane auxetic behaviour, having an effective Poissons ratio (after homogenisation for application in the large-scale optimisation model) ranging from less than zero (auxetic) to around 0.3. By varying the top and bottom surfaces with a smooth variation through the shell thickness all three terms of the A, B, D matrices can be tailored. In addition to this coupling the stiffness can also be varied using the parameterisation method to change the magnitude of the terms.

The shell formulation used in the large-scale model allows non-linear, large deformations to be modelled and optimised for subject to different applied loads or displacements. Both the large and small-scale models apply the finite element method as implemented in FEniCS. Optimisation for the shell response uses sensitivities from the discrete adjoint method. The spatially varying parameters were then reconstructed and printed to produce optimised responses of the shells for a range of different problems (see https://youtu.be/4nbrgUubOKo for an example problem).

Key Words: Multiscale Topology Optimization, Pareto Efficiency, Metamaterials, Surrogate modelling

In recent years, research towards multiscale topology optimization (MTO) has gained interest due to the rapid rise of additive manufacturing techniques. A recent trend in the field of MTO is the focus on families of metamaterials such as lattices with a parametrized unit cell [1]. Usually, these metamaterials are homogenized for varying parameters after which the interpolated homogenized properties are employed for optimization on the macroscale. In case the volume ratio is the only parameter, SIMP-like curves are obtained [2]. Although choosing a predefined microstructure family ensures connectivity and even improves numerical efficiency due to the reduced parameter space, the design optimality is inherently reduced. Indeed, any choice for a certain family of metamaterials restricts the design space, leading to sub-optimal designs.

Although ensuring connectivity and, more generally, manufacturability, is a necessary constraint, it is argued that optimality is often too severely restricted in recent literature. This talk proposes a novel way of looking at metamaterials, allowing for comparison based on their merits in a multiscale homogenization setting. Hereto, the principle of Pareto-optimality is employed by stating that the least a (meta-)material designer can do is ensuring its metamaterials are optimal 'in some homogenized sense'. More specifically, instead of restricting oneself to a family of metamaterials such as lattices with a cubic unit cell, one can and should instead choose the family of Pareto-optimal metamaterials: structures where one cannot improve an element of its homogenized stiffness tensor without jeopardizing either its weight or other stiffness tensor elements.

Such Pareto-optimal materials are then shown to lie on a Pareto frontier, a differentiable, high-dimensional manifold parametrized by the hyperparameters of a novel material design problem. Restricting the microstructural layout, e.g. by using a unit cell described by a low number of parameters, is shown to have severe consequences for the homogenized properties, effectively pushing the Pareto-manifold towards lower performance. Finally, a novel framework for MTO is proposed based on a surrogate model of the Pareto-optimal microstructure manifold. An implementation of this framework is provided and its advantages with respect to optimality, manufacturability and efficiency are highlighted.

Key Words: *Topology Optimization, Multiscale, Multiobjective, Buckling*

With the advances in additive manufacturing components with fine details gain more and more focus. The freedom of design allows for components with solid parts as well as finer substructures like lattices. Two-scale topology optimization, where the general topology is given on a macroscopic scale and finer details, like e.g. infill, are described on a microscopic scale, can help to design such components in an optimized sense with respect to some criteria. Though the use of lattice structures improves a component's compliance only under certain prerequisites, it seems to provide a large enhancement in terms of buckling stiffness of the whole component [1]. However, the introduction of fine details can lead to buckling of individual lattice cells.

In this presentation, we focus on a two-dimensional isotropic lattice structure built out of equilateral triangles, which, in an extruded version, is common as infill in additive manufacturing. To predict the buckling behavior on the level of the individual cells we use homogenization on a representative volume element (RVE), which encompasses more than one cell to also capture modes with a wave length greater than the cell size. We present a worst-case-model describing the cell buckling load factor on the macroscopic scale, which depends on the local porosity of the (possibly graded) lattice and the local stress. The model is developed taking into account uniaxial, biaxial and shear stresses. This enables us to use a scale-decoupled approach in the optimization of a component, which drastically reduces computational cost, but still respects buckling on both scales. We provide numerical results of simultaneous optimization of compliance and buckling on both micro- and macroscopic scale. We conclude with a validation of dehomogenized designs and a comparison of the predicted and actual cell buckling load factor.

Key Words: *Bioinspired, architected materials, nacre, micromechanical modelling, Cohesive Zone Model, Additive Manufacturing*

Natural materials, such as nacre, often exhibit exceptional combinations of properties, which is a result of the specific geometric arrangement of multiple materials across multiple length scales. One particular design motif that has been observed in nature is the Brick-and-Mortar structure, which is charaterised by stiff, discrete bricks in a staggered arrangement and a soft interfacial material between the bricks. Materials with this design motif commonly exhibit simultaneously high toughness and high strength, providing a motivation to replicate the motif synthetically. Synthetic replication of these structures has been made possible recently with the rise of multi-material additive manufacturing, which allows for high spatial control of multiple materials in a single part. To effectively utilize the synthetically manufactured Brick-and-Mortar structures for applications, a good understanding of the structure-property relationship, and underlying deformation mechanisms, is required.

In this work we present a finite-sized micromechanical-based analytical model to study the effect of the geometry of brick shapes on failure regimes of Brick-and-Mortar structures. The proposed model utilises the Cohesive Zone Model to capture the behaviour of the soft phase. It will be shown that such composite structures exhibit 'two-peak' and 'peak-plateau-peak' failure, differing in their ability to distribute damage through the normal layers prior to failure. Furthermore, we demonstrate that these failure regimes can be controlled by varying the angle of the shear layer with respect to the normal layer. We further extend the modelling of the Brick-and-Mortar structure to FEA, utilizing the Cohesive Zone Model, to better predict the composite properties, as well as to extend our prediction of failure regimes to 3D shapes. The prediction of trends in the failure regimes, and the corresponding composite properties, are validated with experiments using Additive Manufactured Brick-and-Mortar structures.

Abstract: The diversity of protein function depends on a local structure derived from the primary amino acid sequence. Structural proteins are the foundation of many biomaterials and is also key constructors and functional components of all life. As the function of protein is determined by its folding structure of a tertiary structure, we try to control the secondary structure content to design the functional protein we want. The primary structure will affect the secondary structure and then affect its tertiary structure. However, it's difficult to design its tertiary structure directly. Here, we provide a deep learning model not only can predict the secondary structure content of the protein from the primary sequence, but also can rearrange the amino acid sequence in the primary structure of the protein to generate a new protein structure with the desired secondary structure content. The secondary structure content of the protein is essential to design a target material function, especially the protein of mechanical properties. Alpha helix and beta sheet are the two most common secondary structures, we use convolution and circulating architecture and natural language models, which can predict the contents of these two basic types of secondary structures, and through the genetics algorithm model rearrange the amino acid sequence in the protein primary structure to generate a new protein structure having the desired secondary structure content. The alpha helix and beta sheet content predictions show excellent agreement with training data and newly deposited protein structures that were recently identified and which were not included in the original training set, and we also generate new primary structure of protein with target secondary structure content successfully. Our model can be widely used in the development of any drugs, vaccines, proteins and other biological material, and be applied to material design and development and other biomedical industries.

Design, Modeling, and Manufacturing of Nature-Inspired Architected Materials Through Unsupervised Deep Learning

Key Words: *Machine Learning, GAN, Bioinspired, Architected Materials*

The design of materials inspired by nature is an emergent topic of great interest, pushing the envelope to create a variety of new material platforms for sustainable technologies. This is motivated by the nature-inspired design paradigm: nature has succeeded in creating strong and tough materials out of weaker organic or ceramic building blocks by architecting them at multiple scales, and as such, innovation can be accelerated by harnessing nature's design principles through biomimicry and beyond, exploiting these principles in novel designs further optimized for human and societal needs[1]. Here we report the development of a deep learning-based approach using a manipulable GAN model[2,3] that enables the generation of de novo 2D and 3D material structures with an inverse tomography approach. The GAN model is used to generate, through movements in latent space, continuous slices of images that are tiled into engineered quasi-2D materials, or reconstructed into 3D geometries that can be further modeled and manufactured using 3D printing. Not only can the concept be used to construct novel materials that mimic natural designs, it also allows for a transfer of information across manifestations, using the latent space as the mediator. This enables us to use information from disparate sources to be translated into material designs. We illustrate the concept here for new materials inspired by leaf microstructures, showing how biological 2D structures can be used to develop novel architected materials in 2 and 3 dimensions. With further refinement and engineering, this work opens new avenues for nature-inspired materials beyond the traditional inspiration or mimicking of natural systems.

Key Words: *Multiscale modeling, Bioinspired design, Extreme material deformability, Intermediate filament networks, Cytoskeletal mechanics*

Material applications involving large cyclic deformations are ubiquitous, ranging from consumer's goods to soft actuators and novel biomedical devices. Epithelial monolayers – cohesive cellular sheets commonly attached to a matrix and lining free surfaces – face similar challenges. The need to repeatedly withstand large deformations has led evolution to refine the structural arrangement of key cytoskeletal components (actin, microtubules, and intermediate filaments (IFs)) and hierarchical motifs (*e.g.* coiled-coils). Recent work highlighted that actin dilution in superstretched cells is accompanied by massive rearrangement of the IF network, whose entangled filaments eventually form a central knot and thick radial bundles that allow cell sheets to cope with extreme deformations [1, 2]. These multiscale characteristics, whereby the structural components may selectively yield, reorganize, and eventually recover, are reminiscent of recently-developed soft materials with unprecedented deformability, toughness, fatigue threshold, and low hysteresis [3, 4].

Inspired by this fascinating parallel between a technical and biophysical problem, we address the design of extremely deformable materials using concepts from epithelial IF networks. Borrowing from mechanics, geometry, and topology, we reverse-engineer the multiscale organization of entangled IF networks and define the conditions that lead to the formation of a stable central knot, enabling load bearing. Our analysis yields a rational link between the emerging material response under cyclic loading and the number, length, constitutive behavior, and degree of entanglement of IF bundles. Ultimately, we propose bioinspired design principles that allow tuning the macroscopic behavior of extremely deformable materials in view of specific applications requirements.

Key Words: *Bioinspired, Lattice, Hierarchy, Topology, 3D printing, Additive manufacturing*

Nature is a stunning example of how–through the design and self-assembly of heterogeneous hierarchical structures–it is possible to combine and amplify the properties of the constituent building blocks of biological materials and optimize such materials for the environment in which they must survive. As evolution continues to drive the adaptive process of making natural materials over time, engineering is now attempting to emulate this extraordinary capability, lately via lattice materials and 3D printing techniques. Indeed, it is well known that, through the combination of optimized cellular architectures, high-performance lightweight materials with optimal combinations of high strength-to-weight and stiffness-to-weight ratios can be fabricated. However, the realization of such complex hierarchical structures with a micro- to macro-scale precision is still a challenge that can only be overcome with state-of-the-art additive manufacturing techniques. Despite the new widespread interest in lattice and hierarchical structures and the recent progress in the field of these materials, many concerns remain regarding their structural integrity due to the lack of well-structured guidelines for their design and a property database to assist in this process. The present research, therefore, aims to fill a portion of this knowledge gap through understanding how the effects of topology, hierarchical organization, and material distribution affect the mechanical properties of a simple design domain, here used as a case study. To this end, we adopt a comprehensive approach that combines computational mechanics approaches with additive manufacturing routes. We consider a beam subjected to four-point bending as a meso-structure. We select two unit cells with contrasting behavior, a bending dominated (single cubic) and a stretching dominated (face-centered cubic), and devise four different designs by introducing these unit cells within the design space. The various designs are created via a modular reconstruction with the ANSYS Mechanical APDL finite element software. The struts of the unitary cells are discretized with beam type finite elements and, through linear analysis, the relationship between structure and stiffness/weight ratio is analyzed. The outcome of this study allows us the probe the effect of the hierarchy, the effect of topology, relative density, and slenderness ratio (SR) of the strut on the overall mechanical behavior of the beam. In particular, we notice how the introduction different hierarchical levels may not be beneficial; this is even more evident when stretching dominated structures are involved. Instead, in the case of bending dominated structure the numerical study shows how the addition of further hierarchical levels can increase the stiffness performances, for low values of SR.

Key Words: *Bone, Cement Line, Damage Propagation, Architectured Materials*

Economic and environmental constraints are triggering the development of materials with enhanced mechanical efficiency and reduced over-dimensioning. These challenges can be met with so-called architectured materials, which have well controlled structural features sitting at intermediate length scales between overall component size and microstructure. However, architectured materials often contain potentially weak spots such as pores and interfaces, which can trigger damage. To minimize and predict failure in these materials, it can be instructive to consider how nature has coped with such problems. As an example, bone is a biological material that not only tries to minimize failure, but can also tolerate and repair damage. One essential feature enabling bone renewal is the presence of an intricate multiscale porosity to house blood vessels and cells. As a consequence, bone must avoid that stress concentrations around pores cause failure. Moreover, cracks forming due to daily loading must not reach the functional pores. In cortical bone, blood vessels are accommodated in the central canals of osteons, which are cylindrical features consisting of several concentric layers of bone lamellae and bordered by a thin protective sheet, called cement line. Osteons are important for bone toughness as incoming cracks can be deflected by the cement line or twisted by the lamellae. In our study, we combine computational modeling with 3D printing to explore the mechanical behavior of osteon-inspired materials. In analogy with the cement line in bone, the protective role of interlayers around a weak region is characterized using damage-based finite element analysis, which assumes that a critical equivalent plastic strain is needed to initiate damage and that damage evolution is controlled by a specific energy [1]. Increasing damage decreases stiffness and strength. We designed 2D notched models featuring a homogeneous matrix with a central hole, bordered by a thin interlayer. We systematically varied the position of the notch with respect to the hole as well as interlayer stiffness, yield stress and fracture energy. After finding the critical notch position that causes a crack to reach the hole, we introduced the interlayer around the hole and we investigated damage behavior. Our results indicate that even a minimal interlayer (having a thickness one order of magnitude smaller than the diameter of the hole) can have a large and non-trivial impact on damage mechanisms, influencing the interaction between the crack and the hole. Interlayers with yield stress smaller than matrix strength are able to trap damage, thus shielding the weak spot. Interlayers more compliant than the matrix can hamper the propagation of cracks after reaching the hole. We used 3D polyjet printing to prototype selected models with interlayers (cement line) printed using different material (stronger or weaker) than the matrix. Our prototypes showed a programmable failure behavior dependent on interlayer properties. This work demonstrates that bone's design strategy to hamper damage can be translated to higher length scales, even using completely different building blocks, into 3D-printed synthetic materials.

Keywords: *Lode; TPMS; Metamaterials; Yield Surface.*

Due to the advancements in additive manufacturing and increased applications of additive manufactured structures, it is essential to fully understand both the elastic and plastic behavior of bio-inspired cellular materials, which include the mathematically-driven sheet/shell lattices based on triply periodic minimal surface (TPMS) that have received significant attention recently. The compressive elastic and plastic behaviors have been well established for many TPMS latticed structures, but not under multiaxial loading. Furthermore, TPMS lattices are computationally expensive to model explicitly (i.e., micromechanical) when used in latticing various structures for enhanced multi-functionality, and hence the need to develop an accurate yield surface function or criterion in order to model their plastic behavior in a homogenized approach. The majority of previous yield surfaces developed for cellular materials were developed for cellular foams [1, 2], and very few attempts has been made to develop a yield surface based on cellular lattices [3]. Furthermore, some of the few studies [4] that used the yield surfaces developed for foams to predict the yielding of cellular lattices, have found that such yield surfaces do not predict well the yielding of lattice structures under various multiaxial loading conditions. In this study, an initial yield surface is developed for sheet TPMS cellular lattices, which to our-best knowledge has never been attempted before, and is compared to the major yield surfaces that have been developed for cellular materials. The effect of different loading conditions on the effective yield strength of IWP sheet-based (IWP-S) TPMS lattice is numerically investigated. The simulations are based on a single unit cell of IWP-S under periodic boundary conditions, assuming an elastic-perfectly plastic behavior of the base material, for relative densities ($\bar{\rho}$) ranging from 7% to 28%. In order to account for the different loading conditions, the Lode parameter (L) is used [5]. The effect of L is studied over a range of mean stress values (σ_m) to understand the effect of both L and σ_m on the effective yield strength. In the plane of the von Mises equivalent stress σ_{VM} versus σ_m, σ_{VM} is maximum at $\sigma_m = 0$ and reduces in a parabolic and nearly symmetric manner with $\pm\sigma_m$ values. On the other hand, in the plane of σ_{VM} versus L, σ_{VM} is minimum at $L = 0$ and increases in a parabolic and nearly symmetric manner with $\pm L$ values. Using these relationships, the effective yield surface for IWP-S is characterized by σ_{VM}, the mean stress σ_m, L and $\bar{\rho}$. In the 3D space of the principal stresses, this yield surface is best described as a cocoa pod. The current developed framework can be adapted for generating yield surfaces for other lattice topologies.

Across time, Natural materials have adapted to their environments by developing a wide arrange of features (*e.g.,* functional gradients, multi-hierarchical organization) [1]. Today, voxel-based or bitmap additive manufacturing (AM, =3D printing) [2] allows incorporating such natural design paradigms into biomimetic composites with complex microarchitectures [3]. This technology uses stacks of binary images to define a composite, where each white or black pixel represents either 'hard' or 'soft' material deposition. However, large voxel counts and complex features make modeling the mechanics of such biomimetic structures extremely challenging and time-consuming. Here, we propose a novel coarse-graining approach based on non-linear foam-based constitutive equations [4] to facilitate the computational modeling of complex biomimetic composites at coarser length scales while maintaining the mechanical response of the composite at high resolution.

To determine the coefficients of the constitutive equations, we used data obtained from standard tensile tests of various composites with different hard material volume fractions (ρ). We additively manufactured these specimens using polyjet 3D printing techniques (Stratasys, USA) and tested them under tensile loading conditions while recording their deformations using digital image correlation. We used non-linear regression fit on the stress *vs.* strain data to determine the parameters of the foam-based constitutive equations. This process enabled us to predict the response of composites within the entire non-linear design space as a function of ρ. We used non-linear finite element code (Abaqus v.6.14) to perform numerical validations of these tensile tests.

Furthermore, we assessed and validated the performance of our coarse-graining approach by comparing our computational models with those of crack (mode I) experiments on biomimetic designs. These tests validated that this coarse-graining approach retains adequate mechanical response of a bitmap design while reducing computation times, even when complex features are present. Thus, the proposed approach offers a rapid, accurate, and reliable tool for designing, modeling, and optimizing advanced engineered biomimetic materials with tailor-made properties.

Key Words: *Biomaterials, sonification, protein folding, molecular dynamics*

Biomaterials, especially proteins, bear many striking similarities to music that can be observed in how both exhibit long-range patterns and hierarchical constructions across time and length scales. They are both increasingly intricate yet neatly ordered networks built from smaller individual units, and thus, music can present a radical paradigm for further understanding the complexities of these biomaterials. Such relationships between music and biomaterials have been previously demonstrated in the sonification of existing proteins and the creation of an amino acid 'scale' via the ranking of vibrational modes. In this study, we present an algorithmic method for translating classical music, specifically excerpts of Leonard Bernstein's "Chichester Psalms", to de novo protein sequences to further elucidate the potential for existing composed musical language as a basis for biomaterial design. This case study also provides a pilot investigation into the capabilities of various predictive protein folding methods like trRosetta and the newly introduced AlphaFold2 for folding de novo sequences with no existing native counterparts. Moreover, the 3D predicted models provide the basis for an iterative generation of new sequences as well as an opportunity to create new musical compositions based on folding patterns and protein contacts. We further analyze the resulting protein structure models and sequences through MD simulation and comprehensive taxonomic profiles of the sequences made using BLAST reveal numerous sequence similarities to native bacterial and eukaryotic organisms. This endeavor demonstrates how understanding proteins within the framework of musical form and language opens doors to a holistic and revolutionary approach to functional biomaterial design.

A high-precision partition coupled Eulerian-Lagrangian method for compressible fluid with large deformation

Jianguo Ning[1], Ziyan Jin[2*] and Xiangzhao Xu[3]

[1] Beijing Institute of Technology, China 100081, jgning@bit.edu.cn
[2] Beijing Institute of Technology, China 100081, 3120195122@bit.edu.cn
[1] Beijing Institute of Technology, China 100081, xzxu@bit.edu.cn

Key Words: *Coupled Eulerian-Lagrangian method, Interface capturing, Compressible fluid, Partition weighted bidirectional mapping*

In the past few decades, numerical methods of solving hyperbolic conservation equations can be divided into Lagrangian and Eulerian methods. The Eulerian method is suitable for simulating fluid flow with large deformation, but often smoothed out discontinuities too much due to the limited number of grids. The Lagrangian method can avoid the numerical dissipation caused by the convection term, but the grid will be distorted and cause large errors. Although both Lagrangian method and Eulerian method have their own unavoidable difficulties, they can be combined in a certain way to give full play to their respective advantages.

A partition coupled Eulerian-Lagrangian method (referred to as PCELM) is applied to accurately track the interface and the contact discontinuity of the compressible fluid with large deformation. This method arranges splittable Lagrangian particles on the Eulerian grid to automatically track the discontinuous points, and adopts the partition weighted bidirectional mapping between the particles and the grids by using cubic interpolation function, which maintain the steep discontinuous transition in the discontinuous area. The partition weighted bidirectional mapping method weights the shape function by the coincident volume fraction of the particle domain and the grid domain, to improve the mapping accuracy and eliminate the oscillation across the grid. The PCELM avoids the the grid distortion problem of Lagrangian method, and makes up for the defect that the Eulerian method cannot accurately track the interface, so that it can accurately capture the contact discontinuity and the free interface.

Then the virtual particle method is introduced to solve the discontinuity of particles at the flow boundary, and to realize the inflow and outflow of particles and maintain the interpolation accuracy of the boundary. Aiming at the numerical fracture problem, the particle splitting method is developed to deal with the violent stretching of the particle.

Finally, a number of numerical tests are used to demonstrate the advantages of PCELM in capturing interfaces and discontinuities. The accuracy test shows that the CELM has fourth-order convergence accuracy, and the norm error of it is lower than that of WENO3 and WENO5 at lower grid numbers. Compared with WNEO3 and WNEO5, SOD and Woodward-Colella test shows that CELM can accurately tracks the shock wave and discontinuity by particles, and the value on the discontinuity is closer to the precise solution and the reference solution, and has lower dissipation. The dam break problem shows small gap between results of PCELM and experimental results, which reflects the advantage of particles tracking the free interface. The two-dimensional Riemann tests reflects shock wave resolution of different schemes. Also compared with WENO3 and WENO5, PCELM can obviously simulate the fine structure of the shock wave at a lower grid number, which reflects its low dissipation characteristics and the advantages of high-precision shock wave capture.

Agglomeration Regimes of Particles in Shear Flow

Y. Qian[1,2*], SP. Usher[1], PJ Scales[1], AD. Stickland[1], A. Alexiadis[2]

[1] Department of Chemical Engineering, The University of Melbourne, Victoria 3010 Australia

[2] School of Chemical Engineering, University of Birmingham, Birmingham, B15 2TT, West Midlands, UK

Key Words: *Particle Agglomeration, Smoothed Particle Hydrodynamics, Discrete Element Method, Dewatering*

Summary: In the mining industry, particle aggregation phenomena in solid-liquid separation are beneficial to accelerate slurry dewatering and improve the performance of thickening and filtration operations. The structural characterization of solid particle agglomeration is an essential part of optimizing the design of dewatering systems and can be investigated using particle-scale simulation. An atlas of different structural shapes of solid particle aggregates under different Reynolds numbers and inter-particle pair potentials can be generated based on the assumption that the solid-solid particle interaction is described by a given Lennard-Jones potential [1]. However, this assumption cannot accurately reflect the contact and adhesion behavior of solid particles.

In our computational simulation tool, a more accurate contact adhesion model was adopted to represent the interaction of solid particles by using Discrete Element Method (DEM). The fluid is modeled with Smoothed Particle Hydrodynamics (SPH). A combined SPH-DEM model is proposed here to model particle agglomeration in shear flow. The system is governed by three fundamental dimensionless groups: the Reynolds number *Re*, which measures the effect of the hydrodynamics; the Adhesion number *Ad*, which measures the 'stickiness' of the particles; and the solid fraction α, which measures the concentration of particles. Based on these three dimensionless groups, several agglomeration regimes are found in Figure 1. Within these regimes, the aggregates can have different sizes and shapes that go from long thread-like structures to compact spheroids. The effect of the particle-particle agglomeration model (Johnson–Kendall–Roberts or Derjaguin–Muller–Toporov) is also investigated. Once *Re*, *Ad* and α are known, the results are combined into 'agglomeration maps', which allow for a quick determination of the agglomerate type.

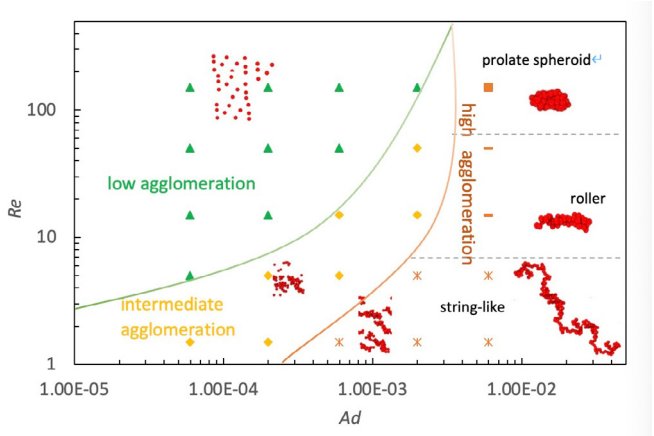

Figure 1: Agglomeration regime map. Illustrating the observed cases as a function of Reynolds and adhesion numbers at a solid particle volume fraction 4.2%.

Development of Efficient and Accurate Simulation Method for Chemical Conversion Treatment Phenomena

Junam KWON[1], Kenji AMAYA[1], Masahiro NAKAJIMA[2], Miku GOTO[2], Hidekazu FUKUSHI[2]

[1] Tokyo Institute of Technology, amaya@sc.e.titech.ac.jp
[2] Nihon Parkerizing Co., Ltd.

Key Words: Chemical Conversion Treatment, Etching, Solid Fluid Interface, Finite Differential Method

The chemical conversion treatment is a method for preventing rust and corrosion by a film precipitation reaction induced by an etching reaction on a metal surface, and is used for surface treatment of automobiles. Examples of the chemical conversion treatment include zinc phosphate treatment and zirconium chemical conversion treatment. Application of numerical simulations to the development of chemical conversion treatment agents is useful for understanding of the mechanism of the phenomenon and shortening of development time. On the other hand, in the chemical conversion treatment, the reaction is concentrated in the very thin boundary layer on the surface of the material and a steep concentration gradient is formed at the initial stage of the reaction. The naive application of the conventional method leads problems of error and increase in calculation time. In this study, we have developed an efficient and accurate finite differential method for chemical conversion processing. That is, we proposed a method to improve the analysis accuracy of the inlet, metal surface, and the region of the initial state where the reaction is intense by converting the spatiotemporal variable in the numerical analysis of chemical conversion treatment into an exponential function. In order to verify the effectiveness of the proposed method, the etching phenomenon of the steel sheet with an acidic solution was analyzed.
